medical science it was necessary to consider the subject as related to medical education, medical practice, including diagnosis and treatment, and preventive medicine. The last was usually regarded as the chief function of the Health Department, and by not a few the sole function. Those who held this view resented what they regarded as encroachment upon their domain. Dr. Nicoll showed the untenability of this attitude of mind. The State Department of Health had sought, and received without seeking, a fair amount of advice and some criticism which had always been given careful consideration which frequently resulted in conformational action by change of method. In turn the Department of Health had not hesitated to call attention to facts regarding medical practice and education which had come within the knowledge of its administrative head and members of staff, and such matters were of equal interest to the practitioner and the medical educator since they involved the health, happiness, and life of the people. Dr. Nicoll then reviewed the outstanding features relating to medical practice, especially those affecting the less populous districts, which he declared were susceptible of confirmation, and so far as he knew had not been convincingly refuted. Physicians were abandoning the rural districts. From 1911 to 1919, the rural districts of the State had lost by removal and death 403 physicians or 13.5 per cent., while the population had increased approximately 7 per cent. Death and dissatisfaction with rural practice had left the field to be covered by middle-aged and old practitioners with few or no recruits ready to take their places. It was claimed that with the improvement of roads and the general use of automobiles fewer physicians were needed. That was true, but many large areas were not covered except by sending for a physician from a long distance. Some 83 communities had appealed to the State Department of Health to send them a physician. The Department had furnished 36 physicians, and 34 localities were still, at last account, without a physician. It was probable that the number of applicants for physicians did not represent the number of communities really in need of medical service. In these rural communities a physician might count upon a better than an average income. The failure of physicians to undertake rural practice was due to the world-wide psychological phase through which civilization was passing, and to which a tremendous impetus was given by the war, which caused the overturning of old standards and habits of life, a desire for constant excitement, a spirit of restlessness which had by no means disappeared at this time. Thus hundreds of physicians who had been in the service experienced a life previously unknown and dreaded to return to the private practice of medicine in rural communities. Such men sought city life, where they could get the excitement they craved. A second reason for the dearth of physicians in rural localities was the great advance in medical science during the last decade and the technical knowledge and equipment frequently necessary to arrive at a correct diagnosis. A third reason for the situation was that there was no question that the life of a rural physician was a hard one, and men today were perhaps less likely to undergo physical hardship than were those of bygone days. A further reason might be found in the increase of specialization as a natural consequence of great knowledge regarding pathological conditions and the new methods. To the undergraduate and young physician specialization with its regular hours, larger fees, and the possibility of establishing a wider reputation made a stronger appeal than did rural practice. Lastly, not only the physician himself but his family often determined his decision. As to possible remedies, Dr. Nicoll said that for the past two years the State Department of Health had introduced a measure into the Legislature designed as a possible solution of the above problem. These were the bills known as the Health Center bills. Secondly, small medical schools must be fostered, encouraged, and their financial needs provided for. A recent study revealed the fact that of 1700 graduates of the Albany Medical School, only 174 had settled in or about New York, while more than one-third had taken up practice in communities of about 10,000. In the natural course of events it was quite doubtful if the average physician would be able to secure an adequate financial

return in the cities, and inevitably he would be forced to seek smaller cities and rural communities.

The Group Consultation Clinic Experiment.—Dr. EDMUND C. BODDY of Rochester read this paper. He stated that there were many industrial and social conditions demanding readjustment that had a direct bearing upon the subject of the scarcity of practitioners of medicine in rural sections, but it must be recognized that an effective development in social advance could not be obtained without a corresponding advance in the standard of physical and mental well-being of our people. It was believed that factors medical should go hand in hand with the social and economic, and it would be apparent to those who gave the existing conditions careful consideration that one of the factors which thinned the ranks of rural physicians was that when, after years of superactive life they were obliged by advancing years to lessen their activities, there was not found readily anyone to share their burdens, and in the event of death the communities which they had served so faithfully had to depend upon already overworked physicians from neighboring towns for their future medical service. It was believed that it was the lack of those facilities which, as a result of the teachings of modern medical schools, and the practice of modern hospitals were essential to the practice of medicine today, that restrained the younger practitioner from choosing the less thickly settled communities for his initial endeavors in the practice of his chosen profession. Public opinion had been aroused to the fact that a larger proportion of our people were suffering from physical handicaps and that many crippling defects might have been prevented had they been recognized and proper precautions taken during their incipency. In trying out the group consultation clinic it was doubtful whether the Commissioner was actuated by the tendency of the practice of medicine to develop along these lines rather than to utilize those facilities which had already been inaugurated and developed, namely, the State Department of Health, the State Department of Education, State Hospital Commission, State Commission for Mental Defectives, State Charities Aid Association, and American Red Cross. The administration of these clinics was experimental. Six clinics were held in series of twos, differing from each other in method of reaching the people and receiving patients. In conducting the first two popular publicity was used in advertising the clinic; admission was granted to all those who presented themselves for examination; the name of the family physician was secured and the report of the examining physician forwarded to him. The second series was conducted with popular publicity, but a card of admission was required, signed by the attending physician, and all reports of examinations were forwarded to him. In the third series all publicity of any character was omitted except that directly among the physicians who were invited to send to the clinic any patient on whose case they desired consultation. Local physicians were invited to attend and to confer with the consultant if they so desired. These clinics were held in seven counties, serving a population of 325,474; the total number of patients examined was 1,735, and the total number of consultations was 3,288. To the first clinics of popular character no doubt many came out of curiosity and no doubt there were some objectionable features which were eliminated from the later clinics. As to the reception of group consultation clinics by physicians, it must be frankly stated that it was a matter of doubt. Many physicians who had attended the clinic had expressed themselves as well pleased with the idea and the service rendered; on the other hand criticism was heard as to benefits obtained. Some of these criticisms were constructive and helpful but many were based upon a misconception of the experiment. Many who had much to say in favor of child welfare clinics, tuberculosis clinics, venereal clinics, clinics for the after care of poliomyelitis, etc., criticised the consultation clinics, which were simply a grouping under one administrative head of these various clinics. It was never claimed that the Department of Health was sending out a wonderful assemblage of eminent specialists who were the last word in their art. The consultants, however, who rendered service were all well known medical men who had devoted special attention to their

respective lines of work. It was contended that a group of medical men making up a clinic so cooperating that an expression of an opinion might be obtained from each as to the condition found upon examination of the patient, aided by the use of the x-ray and well equipped diagnostic laboratory, could give a service that would be acceptable to the physician and appreciated by the public. It was not maintained that a group consultation clinic in itself would answer all the needs of a community for adequate medical service but rather that it would point the way by demonstrating to physicians and the general public how they might develop the idea, utilizing those agencies which existed in the community, by cooperating their activities in one center of administration and providing adequate means for their execution. From this focus might extend in turn such assistance as would enable medical men to supply for the community an adequate medical service.

Dr. NICOLL stated that the county medical societies were not consulted at all. They had endeavored to reach the various practitioners, and stated that they proposed to hold a clinic. On account of the expense to the Health Department there would be one more clinic held, after which there would be no more.

The Abolition of Venereal Disease.—Dr. GEORGE WALKER of Baltimore made this presentation in which he stated that he had had the opportunity in France of being connected with the venereal disease section and was overseas twenty-seven months, where he had charge of the port towns, having succeeded Dr. Young. The second million men sent over showed a little over 5 per cent. of venereal disease and that meant frank lesions with a gonorrheal discharge or the open lesions of syphilis and chancre. That was not comparable to the finding in 1,100 consecutive white patients at the Johns Hopkins Clinic, who showed 11 per cent. of venereal infection; or with 27 per cent. of infections found in the examination of 500 prostitutes in Baltimore; or with the figures shown by 600 jail inmates, among whom there were 16 per cent. of venereal infections in the white and 24 per cent. among the colored, these being apparently healthy persons. In a group of healthy negroes in Texas 24 per cent. were shown to have syphilis. Other figures were quoted to show that syphilis was fairly widespread in the community and was by no means confined to the lower classes. Osler said two years before he died that when a student knew syphilis he knew medicine. He concluded his article with the statement that 20 per cent. of all organic heart lesions were due to syphilis, about 20 per cent. of all nervous diseases, 100 per cent. of locomotor ataxias, 100 per cent. of general paresis, and about 84 per cent. of aneurysms. An English authority had made the statement that syphilis stood in the fourth place of the mortality list in England. Dr. Welch said he was disposed to go a little further and to give syphilis the third place on the list. About the incidence of gonorrhea they knew very little that was exact, but they knew that in the army in Great Britain and France gonorrhea was five times more prevalent than syphilis. When he went to France with the first contingent, in June, 1917, France was not prepared to receive us. There were no restrictions on alcoholic beverages; they were as free as water and prostitution was equally so. It soon became evident that very drastic measures would be required. They found an annual rate of 240 cases of venereal disease per thousand men and 625 cases per thousand men among negroes. It was estimated that there was 72 per cent. of sex contact among the white men and 90 per cent. among the colored troops. It became evident that they would have to depend upon something else than preachment and the attempt to put the prostitute out of bounds. They found that their chief reliance was upon prophylaxis. This consisted in a 2 per cent. protargol solution injected into the urethra and 33 per cent. calomel ointment applications, rubbed in for three or four minutes. These measures were preceded by washing with soap and water and bichloride solution. As soon as these stations were equipped and the men went to them the venereal disease rate dropped from 240 per 1,000 men to 27 among the white men and to 25 to 35 among the colored men for a period of one year. They used moral suasion and punishment, but found that moral suasion had very little effect among the colored men, so they

made it a rule that the colored men should take the prophylaxis whether they had been exposed or not every time they returned from leave of absence. The result was well-nigh miraculous. At the port of Bordeaux they reduced the incidence of venereal disease among the troops to 20 per thousand per year and at other ports similar results were achieved. He felt absolutely certain that if they had stayed long enough and had known a little more about it they could have abolished venereal disease altogether among the troops. In Bordeaux of 126,000 prophylactic applications only 1.4 per cent. were failures. In another port following 9000 consecutive prophylactic treatments there were but 19 infections. In another badly infected port 6524 prophylactic treatments were followed by only 5 infections. In the army as a whole among 224,000 treatments there were 1.3 per cent. failures. Those figures compared with the 240 per 1,000 men without prophylaxis showed what prophylaxis could do. Of one regiment of 3,200 men selected as a body guard for General Pershing, who went to Paris, to London, and back to Paris, and in whom it was not possible to enforce military discipline 13.5 per cent. developed venereal disease. Dr. Walker stated that he was confident in his own mind that in this method of prophylaxis he had a remedy which would practically always prevent venereal disease. He proposed the establishment for the general public of prophylactic stations in all large cities and in suitable places in rural districts, and the introduction of a prophylactic package which could not be obtained at drug stores but only from the department of health, or at these stations, and also the education of the public to see that such prophylaxis was employed. He did not wish to be understood as saying that we should not use methods to prevent sex contact, but that prophylaxis should be applied to those classes that could not be influenced by moral suasion.

Dr. ALEXANDER LAMBERT of New York said he could not allow the occasion to pass without emphasizing the tremendous difference prophylactic treatment had made among the men in the army as a fighting unit. It was a most extraordinary thing to see in the camps where prophylaxis was not employed the enormous number of men laid up with venereal disease and useless for the purpose for which they had been sent over. Prophylaxis of the kind described by Dr. Walker made a difference in the strength of the fighting corps, and this was the factor that finally convinced England, though there was at first a strong sentiment against it at home, that it was a measure worth adopting.

Dr. HENRY S. STARK of New York thought the establishment of prophylactic stations was hardly a thing the section should go on record as favoring at the present time. Most of the facts presented were derived from military life and in civil life one could not apply such data, because in a civil community one did not have the discipline and control that existed in the army. He thought it impossible to do much for the present generation but we could do a good deal for the coming generation by means of proper training and the suppression of all forms of lewdness.

Oral Hygiene.—Dr. HYATT of the Metropolitan Life Insurance Company made this contribution, in which he called attention to the fact that New York spent \$177,000,000 for pure water and that the United States Government had inspectors to insure pure food, but that the public had relegated to a minor place the hygiene of the mouth, through which receptacle all food was passed. Dr. Crowe of England had shown that in an unclean condition of the mouth or in pyorrhea there was a large area exposed to the absorption of toxins and bacteria passing into the body. A small attack of Riggs' disease would have an area equal to three square inches; if all thirty-two teeth were involved there would be an area of absorption equal to eighteen to twenty-two square inches. Over this absorbing surface passed pus, bacteria, and decomposing food; when one thought of this it was not surprising that many systemic disturbances should result from mouth conditions. Dr. Hartzell of Rochester, Minn., had shown that it was possible for infection to work into the pulp chambers of a vital tooth, and had shown the way by which infection traveled. It had been shown that in one milligram of scrapings from a devitalized tooth five to eight hundred million bacteria were found, while

in one milligram of scrapings from a healthy tooth about 5,000,000 bacteria were counted. An examination of 2,000 employees of the Metropolitan Life Insurance Company, one thousand of whom had one, two, three, or four teeth with non-vital pulp and with decalcification around the apical end, and one thousand of whom had no teeth with non-vital pulp, showed a marked difference in the two classes. It was found that among the persons with non-vital teeth many more were suffering from neuralgia and neuritis than among those with no non-vital teeth, the increase in nervous troubles being 164 per cent. There was also a large percentage of tonsil and skin infections, and of those showing albumin in the urine, in the group having non-vital teeth over the other group. Such evidence made it perfectly logical to believe that pathological conditions in the buccal cavity must be associated with systemic disturbances. It was very essential that children in the public schools be instructed and helped to maintain mouth hygiene in its broadest sense.

Dr. ALEXANDER LAMBERT called attention to a group of cases of angina pectoris with high tension arteries, all having a large amount of intestinal gas, and whose feces on examination showed an excessive amount of putrefaction, all of whom had bad teeth. These patients had a high systolic blood pressure, a low diastolic pressure and a great deal of putrefaction, and it was a curious thing that one could not do anything for them until the putrefaction which resulted from swallowing a certain amount of pus every day was stopped. The reduction of the putrefaction in these cases reduced the cardiac pain and improved the general condition. Another fact that had impressed him in this connection was in reference to rheumatic conditions in the young. When he came back to work in the hospital he missed the young rheumatic cases from his wards. He asked the internes how it was that there were none of these. They said it had always been so. They had not been there as long as he had; formerly these cases were plentiful. He went to the record room and looked up 1,000 cases of rheumatism recorded between the years 1906 and 1912, and the average of these cases was 25 per 1,000 admissions right along; today rheumatism in the young furnished only 0.5 per cent, in proportion to other diseases. The only change that had occurred was the change in reference to mouth hygiene and attention to the tonsils. It was interesting to note that while there was a general reduction in the incidence of rheumatism in all ages, the percentage to the total number coming in had remained about the same, except for the age period between 20 and 30, in which not only had the percentage dropped, but the total number had dropped also which was due to the fact that many had lost their tonsils as well as cleaned up their teeth.

Studies on Experimental Measles.—Dr. FRANCIS G. BLAKE of New York presented this communication. (See MEDICAL RECORD, xc, 14, p. 586, April 2, 1921.)

Dr. MATTHIAS NICOLL, Jr., asked Dr. Blake whether they had observed any change in regard to the period during which measles was infectious from that generally accepted. For how many days after the lesions appeared would measles be conveyed? He would also like to know whether the skin lesions alone were able to convey the infection.

Dr. BLAKE replied that in regard to the infectious period they had not made experiments but they had found nothing to indicate any variation from the findings of Anderson and Goldberg. They had found the disease could be communicated six days before the appearance of the exanthema. Most of the animals inoculated within 24 hours after the appearance of the exanthema came down with the disease; of those inoculated on the second day of the rash 50 per cent. showed infection. Anderson and Goldberg established five days after the appearance of the rash as the outside limit of the time during which the infection could be conveyed. However, one must be conservative in applying the results obtained in experimental animals to human beings. It might be that measles was infective for children for a period longer than for monkeys. In reference to the question whether measles could be conveyed by the skin alone, it was impossible to say, for while they had made emulsions from the skin and conveyed the disease it was impossible to say that there was not some capillary blood present.

Miscellany.

FIRST RECORDED CASE OF CHRONIC OBSTRUCTION OF THE DUODENUM, WITH REPORT OF THE AUTOPSY.*

TRANSLATED FROM THE LATIN OF DR. FRIEDRICH BOERNER OF WOLFENBUTEL.

BY JOHN W. BRANNAN, M.D.

NEW YORK.

THE following is a translation of the main portion of an article published in 1752, and probably the first printed record of a case of this nature. The full title is as follows:

FRIDERICI BOERNERI,

Artis Salutaris Doctoris et Practici Wolfenbutelensis. Academiæ Cæsareæ Naturæ Curiosorum et Societatum Teutonicarum Goettingensis, Jenensis et Helmstadiensis Sodalis,

DE TABE SICCA LETHALI

A* Mirabili Duodeni Angustia et Præternaturali Plane Ventriculi Situ.

Disquisitio Anatomico-Medico-Practica Academiæ Naturæ Curiosorum Pensi Ordinarii Loco Oblata, Calendis Novembris, MDCCCLII.

Disquisition on Dry Tabes with Fatal Ending, Caused by a Remarkable Stricture of the Duodenum, with an Abnormal Position of the Stomach, by Dr. Friedrich Boerner, Doctor of the Art of Healing and Practising Physician in Wolfenbutel.

There are so many diseases, of such severity and so difficult to recognize, to which from the very beginning of our lives even to our last breath, we see ourselves, unhappy mortals, everywhere exposed, that to arrest their attack and to restore the body to health, the lifetime of one man scarcely seems to suffice. For if you consider any period of life, even the babe still hidden in the womb of its mother, or little children, or adults, or those who have reached the feebleness of age, or on the other hand, you enumerate all the diseases by which you see the human race surrounded, and their diverse species, which together and in various ways invade the fragile framework of our bodies, you will perceive everywhere dangers innumerable. But how many are still unknown, and how many causes of disease lie concealed, which, unless the bodies of the dead are subjected to the anatomical knife (or as we should say, come to autopsy), cannot be disclosed, and escape even the sharpest-eyed physician.

May it now be permitted to illustrate the above statements, by the present unique case, most worthy of being recorded.

The patient was a man somewhat over fifty years of age, in rather easy circumstances, of bilious temperament, leading for the most part a sedentary life, accustomed to hard and rough food, salted and smoked, such as the people of lower Saxony regard as a delicacy; neglecting ordinary drink, but a strenuous lover of spirits, a man who had persuaded

*Read as part of the discussion on a paper by Dr. E. L. Kellogg on "Chronic Obstruction of the Duodenum Surgically Considered" at a meeting of the Society of Alumni of Bellevue Hospital, January 5, 1921.

himself that about six years before he had been bewitched by an old woman. He afterwards asked the advice of many physicians, and even made use of the remedies of ambulatory doctors who frequent the marketplaces, and men of that character who imagine themselves physicians and are accustomed to make experiments even upon the dying, and whatever they handed out to him he devoured with avidity; at length he came to me and desired counsel and aid against his disease.

He appeared a skeleton and image of death rather than a man. The skin scarcely adhered to his bones, and his whole body from head to heel was wasted away. In the left hypochondrium was to be seen an oblong tumor, resisting but soft, easily movable both above and below, extending from the diaphragm down to the pubes. This he believed to be an egg which the witch had produced by her sorcery. The appetite was nil, and the bowels were persistently obstructed, so that it was only after eight days that a few indurated scybala were brought forth. There was nausea, with inclination to vomit, occasionally even vomiting itself. The pulse was hard, irregular, the sleep disturbed.

After carefully studying the condition of the sick man, who insisted that he had received no external injury, I concluded that his illness was due to an obstruction of the viscera, with atrophy of the stomach, perhaps caused by worms, those dangerous enemies of the *primæ viæ*, and therefore I strove to combat the disease by aperients and gentle evacuants and diluents, and at the same time suitable clysters, but especially by an appropriate diet, to be followed by tonic medicines.

But as happens in illness of long duration, when a happy issue responds slowly to the desire of a sick person, he suddenly and with indignation demanded relief, the hope of which I was not able to give him, and he then said farewell to my treatment and to me; after the manner of the public which is fickle and changeable. About eight weeks later he died, entirely consumed by his disease.

On the day following his death, the opportunity being obtained by chance, the body was subjected to the anatomical knife and opened by a surgeon well trained in his art, in concert with two other distinguished medical men. But oh, what a stupendous spectacle! What a wonderful sight! For when the skin and abdominal muscles had been incised and dissected, there was not a trace of the peritoneum, the omentum, or the mesentery. The canal of the intestines was confused chaos. But in the left hypochondrium from the diaphragm quite to the pubes, behold an oblong membranous sac, spread out and filled with flatus, occupying the whole region! And what was the sac? It was the stomach dislocated from its proper site, corrupted, inverted, passing below the umbilicus and representing a true sac. We then proceed with our search, contemplate the intestines—and behold a new spectacle! for in the duodenum appears a solid and wrinkled constriction, exceeding the thumb in breadth, and so contracted that we are not able to inject through it even the most dilute fluids.

The liver is of normal size but so friable that we can easily crumble it with fingers; of the gall-bladder there is no distinct trace; there is marked hardening of the spleen. The cause of the long illness

and death itself having thus been ascertained, the remaining cavities are not opened. Behold then a most rare but clear case (the truth of which, were I not an eye-witness, I should myself doubt). Behold a dry fatal tabes, caused by a remarkable stricture of the duodenum with an abnormal position of the stomach.

Ancient Roman Medical Jurisprudence.—It is to this aspect of medical science that we must look for the most concrete thinking of the ancient mind on the subject of disease, and fantastic theories and therapeutics were suppressed when medical matters came before the tribunals. The Roman juriconsults discriminated between somatic and psychic maladies, between organic and functional disease, and between disease proper on the one hand and vices or deformities on the other. Transient were distinguished from permanent affections. A vice or cacothēs was with the Greeks a bad habit of body not to be confounded with disease. There were some inconsistencies due in part to different conceptions of disease held by the Greeks. Thus the word *vitium* in Rome seems to have applied to cripples, one-eyed men, etc. But a case is cited in which a lame man was characterized as sick (*morbosus*) instead of vicious (*vitiosus*).

The Future of France.—This subject is discussed in the editorial pages of *La Presse Médicale* for November 10, 1920, xxviii, 82. The marriage rate since the war is most encouraging and in 1919 alone there were 458,000 births. Natality should increase. Writing in 1868 Prévost-Paradol urged that the French multiply rapidly to maintain their place in the world, but this admonition was disregarded. Curiously enough this author warned of approaching economic struggles with the British Empire and the United States but said nothing of Germany. The two countries specified would presumably act more or less in concert, which made the outlook for France more difficult. France must bear in mind the colonizing and missionary activities of England, and also that this colonial and proselytising policy begun by Spain came to grief through its intrinsic defects. The early French colonial achievements also ended disastrously in the loss of Canada and Louisiana and again of India. Great Britain has been the only successful country in this field, and hence it is the Anglo-Saxon who should naturally be feared and emulated. But Great Britain has finished her work and should she succumb, this work will live after her, unchanged by her vicissitudes. Should the loss of her former great transatlantic colonies by France discourage present day attempts? Not at all, for, to go no further, Mediterranean Africa offers great hopes for the future. Morocco, Tunis, and Algiers mean a colonial empire of 5,000,000 French subjects. The colonial Frenchman has none of the birth control disposition of the home people. Look only at the proverbial fertility of the French Canadian, which is utilized in the interests of Great Britain. Next to Mediterranean, Occidental French Africa represents a successful province which sent 200,000 troops to fight for France in the late war. The Frenchman gravitates to warm countries to-day and many thousands live in the European Mediterranean littoral. Therein lies the hope of the future.

FOCAL INFECTION OF THE CERVIX AND ITS RELATION TO SYSTEMIC AND MENTAL DISEASES.*

By FRANCIS WARD LANGSTROTH, JR., M.D.,
NEW YORK.

CONSULTING GYNECOLOGIST TO THE NEW JERSEY STATE HOSPITAL, TRENTON; ASSISTANT SURGEON TO OUT-PATIENTS AND GYNECOLOGIST AT GOUVERNEUR HOSPITAL, NEW YORK.

It seems best to divide the study of this subject into two parts: First—A consideration of all those facts which show that the endometrium of the cervix frequently becomes the site of a focal infection, which is second to no other in its resulting systemic effects. Second—An analysis of the results obtained in fifty cases operated upon for removal of this focus of infection at the New Jersey State Hospital at Trenton.

The writer wishes it understood that he does not claim that by any means all cases of insanity can be cured by simply removing the diseased endometrium of the cervix, nor does he wish this paper to be construed as in any way sensational but the results obtained from this procedure were, in many of the cases operated upon, so pronounced, that he feels it his duty to present the facts to you for your consideration and discussion.

It is necessary for a thorough understanding of this subject of chronic endocervicitis to review briefly the histology of the mucous membrane lining the cervical canal.

The cervical canal is lined with an epithelium different in type and arrangement from that of any other part of the female generative system. Morris's Anatomy states: "The mucous membrane of the neck is thicker and is plicated in the manner already described; its epithelium is ciliated down to the external opening, but there undergoes a transition into the squamous laminated epithelium which covers the intravaginal portion of the os; many racemose mucous glands open into the furrows of the arbor vitæ, and these are liable to pathological changes which cause them to assume a vesicular character when they are sometimes known under the fanciful name of *ovula Nabethi*." Thus we find here in the cervical canal a tissue with corrugations and folds containing deep-seated racemose glands, with tortuous canals the mouths of which are easily obstructed. This mucosa, unlike that of the cavity of the body, is not desquamated with each menstrual cycle.

Considering these histological facts we would

*Read at a meeting of the Section on Obstetrics and Gynecology of the New York Academy of Medicine, February 25, 1921. (See page 894.)

seem to have here in the cervix a tissue well suited to become the permanent abode of pathogenic bacteria, and this has been proven to be a fact. Sturmdorf¹ has shown photomicrographs of the cervical endometrium from cases suffering from chronic endocervicitis, which show all the classic signs of inflammation due to bacterial invasion.

The writer has had numerous pieces of cervical endometrium cultured by the direct method in the laboratory at the New Jersey State Hospital at Trenton, and almost all of them produced a growth of pathogenic bacteria. Besides the direct method, the writer has taken numerous cultures from the cervix by the swab method, after having sterilized the external os, and has received positive reports in practically all cases which showed the clinical signs of chronic endocervicitis. In a previous paper² he reports the results of swab cultures taken from sixty cases of chronic endocervicitis, and it seems that these results are of sufficient importance to repeat them here. "An analysis of the growths obtained from these cultures showed the following bacterial findings: Cases cultured, sixty; negative, six; *Streptococcus hemolyticus*, one; *Streptococcus* not specified, nine; *Staphylococcus albus*, four; *Staphylococcus* not specified, three; *Micrococcus albus*, four; *Bacillus coli*, nine; *Bacillus pyocyaneus*, one; common organisms, five; mixed infections, eighteen. Among the mixed infections were found some of these various combinations: 1, A streptococcus and Gram-negative bacteria; 2, Gram-positive and coccus not determined; 3, Streptococcus, staphylococcus and tubercle bacilli; 4, Streptococcus, staphylococcus, and *Bacillus subtilis*; 5, *Bacillus coli* and *B. hoffmanni*; 6, Gram-negative bacillus, *Staphylococcus albus*, and *Bacillus coli*; 7, *Bacillus coli* and Gram negative; 8, *Staphylococcus* and *Bacillus coli*; 9, *Staphylococcus*, streptococcus, and *Bacillus coli*; 10, *Staphylococcus* and smegma bacillus; 11, Streptococcus and *Bacillus coli*; 12, *Micrococcus albus* and Friedlander bacillus; 13, Streptococcus and micrococcus. Gonorrheal infections have not been seen in the series of cases.

Most of the above cultures are distinct from the fifty cases here reported for the first time. These cultures reported for the first time in this paper were all obtained from direct culture in broth media of the cervical endometrium removed at operation and will be analyzed later in the paper.

In proof that these infections are confined to the endometrium of the cervix and practically never involve the endometrium of the body of the uterus we have first the work of Sturmdorf¹ reported in his various papers. And further the work of Curtis and the writer should be considered. Curtis³ found in over 100 uteri examined only a very small

percentage in which bacteria could be isolated from the corporeal endometrium, and it seems probable that in several of these the bacterial flora gained entrance through being forced into the uterus from the tubes, as the same bacteria were found in the tubes. Also in some of these cases the uterus had been curetted during the operation, or at a former operation performed shortly before, so transmitting the bacteria from the cervix into the uterine cavity. As to the histology of the endometrium, he agrees with Hitchman and Adler, whom Sturm Dorf, quoting in 1916, as also Kundrat, says, they "have conclusively proved that nearly all of the histological features generally depicted as endometritis present only the normal endometrial transitions of the menstrual cycle. Even that infrequent form clinically labeled hypertrophic endometritis, more correctly termed glandular hyperplasia, is never inflammatory in character, but a functional adenomatous overgrowth, analogous to that presented by the thyroid in Graves' disease." Curtis quotes Mange, as did Sturm Dorf, in reference to the rarity of finding bacteria in the uterine mucosa. His work is done in a most thorough and satisfying manner, and his deductions seem to coincide with those of Sturm Dorf. In over ninety-five per cent. of some seventy-five cases operated upon by the writer for removal of their infected cervical endometrium, by a method first invented and described by Dr. Sturm Dorf, and reported in a former paper,⁴ the results were most gratifying. These patients were cured of all their pelvic symptoms and their leucorrhea was stopped, besides which they were all markedly benefited in their general health.

It is not the purpose of the writer here as in former papers to show how chronic bacterial invasion of the cervical mucosa produces most of the various pathological lesions of the uterus and other female pelvic organs, which lesions in turn cause many of the symptoms from which women suffer gynecologically. This part of the subject has already been carefully covered by Dr. Sturm Dorf and the writer in the papers quoted above.

The object of this report is to establish the fact that chronic infection of the cervical mucosa with pathogenic bacteria occurs with great frequency and that it then becomes a focus of infection just as prone to cause systemic and mental manifestations as foci in the tonsils, teeth, sinuses, intestinal tract, etc. In fact there is every reason why we should expect these results since the cervix is very freely supplied with blood and lymphatic vessels, into which absorption of toxic products and even bacteria can take place.

It seems advisable to correlate the study of focal infections of the cervical endometrium with focal infections of other parts of the body. Since, despite all the bacteriological and clinical evidence that has been produced in proof of the fact that focal infections can be the cause of severe systemic and mental manifestations and diseases, many, if not the majority, of the medical profession do not yet accept this fact. No doubt much of the uncertainty that exists, in the minds of the medical profession, about focal infections results from the fact that, after a primary focus of infection once occurs, secondary foci are rapidly established, so that it becomes necessary to seek for and eliminate not one

but several foci in most cases before benefit is obtained.

The work of Rosenow, while it may have caused the pendulum to swing too far, is now very generally conceded to have proved the fact that bacteria can become domiciled in certain areas of the body and, without causing much if any local disturbance, be the cause of severe systemic manifestations and diseases. He reported a series of experiments with "organisms corresponding closely with the *Micrococcus rheumaticus*" of Poynton and Payne. He thinks this organism is more virulent than the *Streptococcus viridans* but less virulent than the hemolytic streptococcus and pneumococcus, though these last two do not, however, produce ulcer of the stomach. He describes the various types and virulence that the streptococcus may assume. He obtained the same organisms from the tonsils of several cases. Among the lesions that he mentions that he was enabled to produce from injecting these organisms into animals were "Mild arthritis and endocarditis, and in most of them pericarditis was present but not in marked form. Iritis and conjunctivitis, hemorrhages in the sclera, retina, and iris have been observed repeatedly. Occasionally lesions in the cortex of the brain, frequently punctate hemorrhages in the stomach, followed by ulcer, and hemorrhages in the appendix have been found." In a later article⁵ he closes with the following: "The supposed relation between infected tonsils or gums, and gastric ulcer may be due not to the swallowing of the bacteria as usually supposed, but to the entrance into the blood of streptococci of the proper kind of virulence to produce a local infection in the wall of the stomach, many other observations might be cited such as associate infections of the gall-bladder and appendix, which suggest that gastric ulcer may be due to streptococci.

It is interesting after reviewing this work of Rosenow's to find that in the above reported cultures the streptococcus occurs alone ten times, combined, but not with the colon bacillus, four times, and with the colon bacillus two times, in all sixteen times. The colon bacillus occurs alone nine times, combined but not with the streptococcus, four times, and with the streptococcus two times, making a total of fifteen times. Thus we have twenty-nine of these cases of chronic endocervicitis infected with either the streptococcus or the colon bacillus, and thirteen others in which some form of staphylococcus was found, totaling forty-two in which a virulent infection was present. If then focal infections occur and cause remote effects anywhere, certainly the same is true, in the light of these researches, in regard to the cervical endometrium.

Having now reviewed the histology and bacteriology of chronic endocervicitis, and having compared this focus of infection with foci of infection in other parts of the body, let us turn our attention briefly to some of the clinical aspects of this subject.

During the year 1917 the writer was fortunate in having the opportunity of operating upon some nervous and mental cases for Dr. D. E. Drake at his sanitarium at Newfoundland, N. J., for removal of cervical foci, very satisfactory improvement resulted in these cases. The following year the pres-

ent series of operations was started at the N. J. State Hospital at Trenton, through the courtesy of Dr. Henry A. Cotton, Director.

The present report is a result of this work, and the writer believes that it records the first series of cases operated upon for removal of infective foci in the cervix, with the deliberate purpose in view of relieving some mental or nervous condition or manifestation. Every care was taken to make the work accurate. The findings and recommendations were dictated at the time of examination of the patients and during the operations, and all tissues removed were sent to the laboratory for culture. For the sake of brevity only four histories are given in detail. The whole fifty cases in the series are arranged in the form of a chart from which an analysis of the work can easily be deduced.

CASE No. 29.—R. H., colored woman, age 31, married, five children. Became suddenly excited after the birth of the last baby, in May, 1918. Remained in this condition for several months and was sent to Ward's Island. Recovered from this attack. Onset of second attack was sudden, two months before birth of another child, in May, 1919. She became destructive, noisy, attracted attention on the streets, was put in jail, and finally admitted to the State Hospital in July, 1919. She had badly infected tonsils, which were enucleated. Her stomach test showed streptococcus and colon bacillus infection. On August 19, 1919, plastic conical enucleation of the cervix was done. The cervix was found to be in bad condition and the culture showed a streptococcus and the colon bacillus. One week after this operation she apparently cleared up and at the time of leaving the hospital, September 17, 1919, she was oriented, with full insight and good judgment. She visited the hospital in July, 1920, and reported that she was again pregnant, but that her mental condition was entirely normal. This is the first time she has had a normal mental condition during pregnancy.

CASE No. 35.—S. A., single, girl, aged 19, on her first admission to the State Hospital, December, 1912, had a rather peculiar mental condition, but apparently recovered and after six months went home. She returned October, 1917. Her infected teeth were removed and in December, 1918, four unerupted teeth were extracted and her tonsils removed. Her mental condition improved, but she remained thin and emaciated in appearance. After a visit of a few months at home she returned to the hospital, July, 1919, and was given a stomach test, which showed streptococcus and colon bacillus infection. A full course of vaccine therapy was given, but there was no improvement in the patient's condition. In September, 1919, a plastic conical enucleation of the cervix was performed and there was an immediate change, the patient gaining thirty pounds. Her mental condition is greatly improved.

CASE No. 21.—J. V., married woman, age 27. Admitted to State Hospital March, 1919. Married at the age of 18; had two children. First attack followed birth of child. Onset was rapid. Patient suffered from vertigo, was depressed, and at times violent and suicidal. Eight infected teeth were extracted and her tonsils enucleated. Physical examination showed perineum lacerated second degree, slight rectocele, cystocele, cervix lacerated and congested. Cervical operation was done April, 1919, the culture showing micrococcus albus. Following this operation there was an interesting change in the mental condition of the patient. At first she was greatly depressed and suicidal and needed constant watching. Gradually she became more tractable, her depression cleared up and as soon as she was physically able she was given parole of the grounds. She left the hospital June, 1919, recovered.

CASE No. 22.—D. B., married woman, age 24 when admitted to the State Hospital, July, 1918. Onset of her trouble was said to follow an abortion at three months. She became violent, resistive, destructive, and

suicidal. Was generally considered bright, and graduated from grammar school, but was always stubborn and uncongenial. Her infected teeth were extracted, tonsils enucleated, and her stomach test showed streptococcus infection. She was given autogenous vaccine. In March, 1919, appendectomy and cholecystectomy were performed, and in May a plastic conical enucleation of the cervix was done. The cervical culture showed the colon bacillus. This patient is still in the hospital, her condition practically unimproved.

We find the following interesting facts so far as the bacteriology of these fifty cases is concerned: The stomach and cervical cultures were both complete in thirty-one cases, the stomach culture in thirty-eight and the cervical culture in thirty-nine. In the complete cases we find the same combination of bacteria or the same kind of bacteria if only one is present eight times as follows: Streptococcus and colon bacillus in both the stomach and cervix four times, streptococcus three times, colon bacillus once. In seven other of the cases we find one of the same bacteria present in both the stomach and cervical cultures, either a streptococcus or the colon bacillus, and in three negative cultures from both. Making eighteen or over one-half of the cases, or to be exact 58 per cent., in which the same infection was found both in the stomach and cervix. Does this not point very strongly to either a lymphatic or a hematogenous transference of bacteria? Out of the fifty cases, through some error of routine, no culture from the cervix was taken in nine, two were reported as common organisms, leaving thirty-nine cases with the following bacterial findings: Streptococcus combined with the colon bacillus seven times; streptococcus alone eleven times; colon bacillus alone seven times; staphylococcus or *Micrococcus albus* four times; thus making a total of eighteen cases infected with the streptococcus or forty-four per cent., colon bacillus fourteen infections or thirty-four per cent., and of these two either singly or combined twenty-five or sixty per cent. It is of interest to note how closely these findings agree with those detailed in the first series, and as near as the writer can judge they agree very closely with the findings in his private cases. They likely represent the bacterial flora of chronic infection of the endometrium lining the cervical canal. Of the cases that recovered after operation we find fifty-two per cent. infected with one or both of these same organisms, or if we wish to consider that the two reported as common organisms were not completely worked out and were really infected with one of these bacteria it would bring the total up to sixty-four per cent. The same relation of these two germs was found in the cases improved from the operation, it being sixty-three per cent. It certainly seems more than a coincidence that the percentage of the whole series, the cases benefited and the cases cured, should be so nearly the same for these two types of bacteria.

It is necessary to explain here, in order that the analysis of these cases may be more fully appreciated, that most of this series of cases reached the gynecological service after every other focus of infection that could be found had been removed and vaccines had been administered. This fact was partly due to the routine of the hospital and partly to the fact that the writer's service was only established after the other work was well under way.

Dr. Henry A. Cotton, Chief.

Explanation of Abbreviations

M. D. I.—Manic Depressive Insanity. (Depressed or Manic)
Const. Inf.—Constitutional Inferiority.Exh. Del.—Exhaustion Delirium.
Ap.—Appendectomy.
E. L.—Exploratory Laparotomy.

All the cases exhibited the clinical signs of chronic endocervicitis, with two exceptions; those cases in which the examination indicated the necessity of pelvic work were excluded from this series. An attempt has been made in the chart to distinguish those cases that had an infection in addition to a laceration of the cervix and those that had an infection without laceration by designating the first as Lac. cervix and the latter as Infected cervix. The cervical operation of choice was that first invented and described by Dr. Arnold Sturmdorf which, on account of its descriptive value, acquired the name of plastic conical enucleation of the cervix, at the State Hospital at Trenton; although various methods and modifications were employed. The fundamental object, however, was to remove completely the infected cervical endometrium. In addition to the cervical operations ten perineorrhaphies were performed, in one of which an additional cystocele operation was done and one or both tubes and ovaries were removed in two of the cases. There were no deaths, and a gynecological cure was obtained in practically all the cases with a marked improvement in general health and a gain in weight that was very pronounced in most.

The following mental results were obtained: Eighteen cases were improved after removal of foci in teeth, tonsils, etc., but none were cured. From removal of the focus in the cervix twenty-one cases were improved; fifteen of these had shown no im-

provement from the removal of other foci, the other six had shown some improvement from the former work. After removal of their infected cervical endometrium seventeen cases are reported by the hospital to have recovered mentally; eleven of these showed their first improvement after removal of foci in the teeth, tonsils, etc., the other six cases showed no improvement till the cervix operation was done; then they recovered.

The twenty-one cases improved were of the following mental groups: Unclassified, three; Exhaustion delirium, one; Manic depressive insanity not classified, three; Manic depressive insanity depressed, four; Epilepsy, two; Constitutional inferiority, one; Dementia præcox, three; Paranoid condition, two; Psychasthenia, one; Imbecile, one. The seventeen cases reported cured were as follows: Manic depressive insanity not classified, four; Manic depressive insanity, manic, two; Manic depressive insanity, depressed, five; Toxic psychosis, one; Hypomania, one; Neurasthenia, two; Dementia præcox, one; Unclassified, one.

The writer feels justified in drawing some of the following conclusions from the study of the work:

The cervical endometrium is frequently invaded by pathogenic bacteria and thus becomes a focus of infection which causes alterations in the cell chemistry, due to the absorption of toxins, resulting in marked systemic and mental manifestations and diseases.

*In all cases the lacerated cervix was also infected.

Various types of the streptococcus and colon bacillus, occurring either singly or combined, seem to be the most frequently offending organisms, but harmful results from the presence of the various staphylococci must not be overlooked.

The same kinds and combinations of bacteria are recovered with great frequency from more than one area of the body, as the above analysis plainly shows. This points very strongly to a hematogenous or lymphatic distribution of these bacteria.

Certain portions of the body seem prone to become the site of these foci of infection, partly on account of their histological structure, and partly because their function, especially in the adult, is limited. These areas are largely represented by the tonsils, teeth, especially when the nerve is dead, appendix, cervical endometrium, and, as has been suggested by some, the seminal vesicles and possibly the prostate gland in the male. The colon and gall-bladder would seem to the writer to be the site of secondary rather than primary infections.

The bacteria and toxins of chronic focal infections, are, the writer believes, selective, some showing a predilection for one structure of the body and some for another. This likely explains why some cases having foci of infection suffer from some manifestation perhaps in the joints or intestinal tract, etc., and again others from nervous or mental disturbances.

In order to obtain results all the active foci must be sought out and removed, and vaccines given.

Vaccines or foreign proteins do not seem to be able to destroy the infecting organisms, but do seem to aid in neutralizing and combating the toxins. (It is quite likely that few of the cases reported here would have benefited if the foci in their teeth, tonsils, etc., had not been removed.)

Just as in arthritis, the best results in nervous and mental diseases are obtained when the foci are removed early in the course of the disease; little benefit can be expected when fibrous changes have taken place or nerve tissue has been destroyed.

We are now fully justified as a result of this work in placing focal infections of the cervical endometrium upon a firm basis, second to no other, as a factor in the cause of systemic mental and nervous manifestations and diseases. And while we should not promise too much from a removal of these foci, still no one would seem justified in treating many of the chronic diseases to-day without having all these foci sought for and removed by someone especially trained in the respective field.

The writer wishes to thank Dr. Cotton for the opportunity of performing these operations at the N. J. State Hospital at Trenton; Dr. Stone and other resident physicians for their untiring help and assistance in carrying on this work, and Mrs. Maude B. Rue, statistician, for abstracting the histories. There is also appended a partial list of articles that the writer found valuable in preparing this paper, but to which no opportunity was found to refer to in the paper without increasing its length unduly.

THE ELECTRICAL NATURE OF MAN.

11. ALBERT ABRAMS, A. M., M.D., LL.D.,
SAN FRANCISCO, CAL.

In one of my books, "New Concepts in Diagnosis and Treatment" and elsewhere my technical apparatus, "Electroradiometer" and "Oscillophore" are employed for demonstrating human radiations. The sensitivity of the human reflexes for showing the latter was evidenced by the use of the heart.²

Human Phenomena.—My constant endeavor has been to study man from the viewpoint of physics. Until this is done, medical art can never attain the dignity of a science. A science is gauged by the amount of mathematics (symbolized logic) it contains and when one can neither measure nor express knowledge in numbers, such knowledge is not scientific.

The writer is a positivist in the sense that knowledge should be limited to phenomena, and that all sciences are but branches of one science to be investigated by one and the same method. The antiquated theory of vitalism predicated a vital force unfettered by natural laws thus segregating the human organism from other entities and so retarding the correct interpretation of human phenomena.

Isolation and weighing of an electron eliminates imponderability as the dividing line of material and spiritual matter. The vital force is the inherent radioactivity common to all life evolved from the incessant activity of the electrons.

The yield of this radioactive energy as shown by my apparatus is greatest at birth and diminishes with advancing age.

²"Electrical Experimenter," Sept. 1918; *Physico-Clinical Medicine*, Sept. 1918.

Human Radiation.—Energy liberated by the human appears in mechanical, thermal and electrical form. Apparatus (magnetometer, sthenometer, and a variety of dynamoscopes) for recognizing radiations have been devised but, lacking constancy in action, they are impracticable.

The heretofore supposititious radiations have been called prana, animal and vital magnetism, odyle, psychode, biactinism, aura, etc. Superstition is true psychology with the wrong dress and the electroradiometer shows that some spiritistic phenomena are realities independent of disembodied spirits and referable to the manifestations of human radioactivity. It can be shown that, in the normal male, radiations from the right hand are positive and from the left hand negative and this polarity is reversed in the normal female. Yellow reflected on the body will reverse the normal polarity in both sexes. It can be shown with the electroradiometer that the average man thinks with

FIG. 1.—Cerebral electrogenic centers of the male and female. The decussation of the nerve tracts accounts for the polarity on the opposite side of the body.

only one side of his brain, whereas the genius utilizes both sides.

Electricity.—A few elementary facts in physics are relevant to my subject. Electricity has been arbitrarily divided into static and current; the former is electricity at rest and the latter, electricity in motion. Static electricity is produced by rubbing or the influence of one electrified body on another. Current electricity is produced by batteries and dynamos.

Static electricity is usually considered of minor theoretic importance and the experiments with it are relegated to the juvenile experimenter.

Positive and Negative Electricity.—If a rod of sealing wax or other resinous substance is rubbed with a dry wool cloth, it gains the property of attracting to itself light bodies (pith or bits of paper). After the latter are attracted, they are repelled.

Rubbing produces what is known as a charge. A

glass rod rubbed with silk will attract a pith ball which was repelled by the sealing wax. Thus, one differentiates positive (vitreous) and negative (resinous) electricity.

Bodies charged with one kind of electricity repel those charged with the same kind, but attract those charged with the opposite kind. Charged bodies are said to be excited or electrified.* They are discharged by contact with the finger.

Excations.—To investigate human phenomena, it is necessary for the investigated individual to face the geographical west, with the uninvestigated arm or leg separated (arm from the body and one leg from the other).

Grounding as a rule is unnecessary, but the phenomena are accentuated if a wire is connected with one leg to a radiator or water pipe. All materials must be clean and dry. In moist weather, they must be warmer than the air in the room and parts intended to be electrified must not be handled. Pith may be obtained from any jeweler. Sunflower pith is excellent. Cut out balls with a sharp knife and smooth them by rolling between the hands.

Technique.—Suspend a small pith-ball by a silk thread from a rubber rod. The latter may be held in the hand in a clamp or placed on a table. Charge ball by touching it with a rod of hard rubber rubbed with flannel. When charged the approach of the rubbed rod will repel it.

Observe that any substance with a positive charge will attract the ball and a negative charge will repel it. Observe that if the ball is charged with a rod of glass, the opposite effects ensue.

Only a few experiments will be cited.

Experiment I. Showing that human radiations from the tips of the right hand and foot in a normal male are positive and on the left side negative. That the opposite polarity is present in a normal female. Sexual inclination is a matter of polarity. Seated or standing toward the geographical west, approach the ball with the grouped finger tips. Note that, in repulsion, the primary action is a slight attraction immediately followed by repulsion. These effects may be noted directly or indirectly, by observing the shadow of the ball.

Note that when standing in the magnetic meridian, these effects are not observed until the body approaches the west. When the finger tips of both hands are held on either side in proximity to the ball the latter oscillates to and fro (the action of neutral electrification). Note that in temperamental individuals the polar effects are accentuated.

Experiment II. Showing that the normal polarity may be reversed by yellow light allowed to fall on the body, notably on the head, and that normal polarity effects are accentuated by red.

Experiment III. Showing that polarity may be reversed by a bar magnet. Present negative pole of the magnet to the left side of the head (Fig. 1) in a male and note the reversal of polarity when the right finger tips or toes approach the ball. A like reversal ensues when the positive pole of the magnet approaches the same side of head in a female.

Experiment IV. Showing that zones of polarity

*Further elementary facts may be gleaned from any text book on physics.

are localizable on the body. Normal male and female identification is possible by holding the rubber rod in the hand. When the ball approaches the zones (Fig. 2) peculiar to the male or female, repulsion of the ball ensues, whereas at the other side, there is some attraction. Repulsion is the true test of electrification.

Do not confound the motion of the ball with the unconscious muscular movements of the magic pendulum (*pendule explorateur*) used for determining the sex of eggs, location of underground ores or springs.

If the body approaches the suspended ball from a stationary stand the results are the same.

Experiment V. Proving that friction is necessary to evoke a static charge. All rods show positive and negative ends. The reason why this fact has been unrecognized is because some heat is necessary to accentuate electrification. Take an inanimate object like a rod of wood. Heat both ends slightly in a flame and note that one end approaching the ball will attract and the other end will repel it.

Experiments with magnets (slightly warmed) show when held toward the ball, the latter being thoroughly charged negatively, the following:

Positive pole of a bar magnet attracts, and negative pole, repels. A horseshoe magnet causes the

FIG. 2.—Areas on the abdomen and upper part of the chest peculiar to sex.

oscillations of what is designated by the writer as neutral energy. Note that one of the poles of the horseshoe magnet will attract and the other will repel the ball. This simple differentiation of the poles may be corroborated by the compass needle.

Electronic Reactions of Abrams.—These refer to definite and constant areas of dullness elicited by percussion on the chest and abdomen¹. In the *MEDICAL RECORD* (Feb. 16, 1918), and elsewhere², "Symptomatic Atelectasis" was discussed. The reader is referred to the latter contribution to avoid repetition.

Referring to Fig. 3, the zones peculiar to cancer and syphilis are demarcated. These zones of dullness are evident in every individual with syphilis and carcinoma provided the patient faces the geographical west and is grounded. Separation of the feet and hands extended from the body² will accentuate these areas of dullness.

If a bar magnet is presented to the cancer area during percussion, the dullness persists with the positive pole and is dissipated by the negative pole, showing the positive character of the cancerous energy.

The luetic area is positive and negative inasmuch as the dullness persists with both poles. When a pith ball is suspended from a proper support and the ball is about one inch from the areas in ques-

tion a movement of the ball is noted and this movement varies with the nature of the energy:

1. Positive (cancer)—more attraction than repulsion.
2. Negative—more repulsion than attraction.
3. Neutral (tuberculosis)—A lateral to and from movement.
4. Positive and Negative—Attraction and repulsion in a vertical direction. By use of the ball the zones may be definitely circumscribed.

Note that these oscillations of the ball are not present when the patient faces the magnetic west, but reappear at once when the posture is directly toward the geographical west.

To achieve accuracy in noting the movements of the ball avoid suspending the ball by the fingers to eliminate unconscious muscular movements.

By aid of the electronic reactions employed in various ways, say in syphilis, one may determine the following:

- (1) Differentiation of congenital and acquired syphilis; (2) Potentiality of the disease; (3) Parental origin; (4) When acquired (approximately);

FIG. 3.—Showing the areas of dullness in the interscapular regions: peculiar to cancer (left) and syphilis (right).

- (5) When quiescent; (6) When cured; (7) Site of infection; (8) Strain.

Addendum.—Physicians using the electronic reactions for diagnosis will note that the oscillations of the pith ball will only recur at the vibratory rates of the disease. That the oscillations do not ensue beyond the potentiality of the energy.

That the same method of diagnosis is demonstrable over other areas in different diseases in accordance with their topography as shown in the "Iconography of Electronic Reactions," by Abrams.

Owing to the rejuvenated scientific importance of the pith ball, it is worthy of a more dignified appellation and the neonym "electrobioscope" is proposed. Since this article was written the writer has still further elaborated its uses, enabling him to define with accuracy the topography of the viscera, appendix, location of cerebral centers, etc.

TECHNIQUE OF PSYCHOANALYSIS AS PRACTISED ON A CASE OF PHOBIA.

By H. LAVESON, M.D.,
NEW YORK.

THE patient, a woman about forty years of age, dreaded and tried in consequence to avoid the sight of church steeples and towers of any kind. When she passed by such a tower, she was very strongly affected emotionally, experiencing always a feeling of terror or anguish, accompanied by the usual marked physical symptoms. Sometimes even speaking of a tower would at once awaken this emotional complex which expressed itself outwardly in her face, as I myself observed on several occasions. Considering the frequency with which church and schoolhouse towers are met with in everyday life, one can easily imagine the discomfort arising from such a phobia. Before the mystery was unraveled she was unable to give any explanation of the origin or meaning of this phobia, and could not connect it with any episode in her life, or even state how far back in her life it had existed. Vaguely she thought it existed when she was about fifteen years of age and that it might have existed before that. Now, it should be noted that an idea of a tower with bells had in her mind no meaning whatsoever that explained the fear. It had no more meaning than it would have in anybody's mind. In the content of consciousness there was only the perception plus emotion, and no corresponding meaning. Accordingly, I sought to discover the origin and meaning of the phobia by the so-called psychoanalytic method.

When I attempted to recover the associated memories by this method the mere mention of bells in a tower threw her into a panic in which anxiety, "thrills," and perspiration were prominent. Before making the analysis I had constructed a theory in my mind to the effect that a phobia for bells in a tower was a sexual symbolism, being led to this partly by the suggestiveness of the object and partly by the fact that I had found symbolisms of a sexual kind in her dreams.

Analysis was conducted at great length, and memories covering a wide field of experiences were elicited. When asked to think of bells in a tower, or each of these objects separately, there was at first a complete blocking of thought, in that her mind became a blank. Later, memories which to a large extent, but not wholly, played in various relations around her mother (who is dead) as the central object came into the field of consciousness. Nothing, however, was awakened that gave the slightest meaning to the phobia even on the wildest interpretation. The patient, who had been frequently hypnotized by another physician, tended during the analysis to go into a condition of unusually deep abstraction, to such a degree that on breaking off the analysis she failed to remember, save very imperfectly, the memories elicited. Such an abstraction is hypnosis.

Finally, after all endeavors to discover the genesis of the phobia by analysis were in vain, I tried another method. While she was in hypnosis I put a pencil in her hand with the object of obtaining the desired information through automatic writing. While she was narrating some irrelevant memories

of her mother, the hand rapidly wrote as follows: "G . . . M . . . church and my father took my mother to Bi . . . where she died and we went to Br . . . and they cut my mother. I prayed and cried all the time that she would live and the church bells were always ringing and I hated them."

When she began to write the latter part of this script she became depressed, sad, indeed, anguished; tears flowed down her cheeks and she seemed to be almost heartbroken. In other words, it appeared as if she were subconsciously living over again the period described in the script. I say subconsciously, for she did not know what her hand had written or why she was anguished. During the writing of the first part of the script she was verbally describing other memories; during the latter part she ceased speaking.

After awakening from hypnosis and when she had become composed in her mind, she narrated, at my request, the events referred to in the script. She remembered them clearly, as they happened when she was about fifteen years of age. It appeared that she was staying at that time in G . . . M . . . , a town in England. Her mother, who was seriously ill, was taken to a great surgeon to be operated upon. She herself suffered great anxiety and anguish lest her mother should not recover. She went twice a day to the church to pray for her mother's recovery, and in her anguish declared that if her mother did not recover she would no longer believe in God. The chimes in the tower of the church, which was close to her hotel, sounded every quarter hour; they got on her nerves; she hated them; she could not bear to hear them, and while she was praying they added to her anguish. Ever since this time the ringing of bells has continued to cause a feeling of anguish. This narrative was not accompanied by emotion, as was the automatic script.

It now transpired that it was the ringing of the church bells, or the anticipated ringing of bells, that caused the fear, and not the perception of a tower itself. When she saw a tower she feared lest bells should ring. This was the object of the phobia. She could not explain why she had never before connected her phobia with the episode she described. This failure of association, as we know, is not uncommon, and in this case was apparently related to a determination to put out of mind an unbearable episode associated with so much anguish. There had been for years a more or less constant mental conflict with her phobia. The subject had striven not to think of or look at belfries, churches, schoolhouses, or any towers, or to hear the ringing of their bells, or to talk about them. She had endeavored to protect herself by keeping such ideas out of her mind. Before further analyzing the case there are two points which are well worth calling attention to.

1. When the subject subconsciously described the original childhood experience by automatic script there was intense emotion—fear—which emerged into consciousness without her knowing the reason thereof. When, on the other hand, she later, from her conscious memories, described the same experience, there was no such emotion. In other words, it was only when the conserved residua of the experience functioned consciously and autonomously

as a dissociated, independent process that emotion was manifested. So long as the memories were described from the viewpoint of the matured adult personal consciousness there was no emotion. As a subconscious process they were unmodified by this later viewpoint. This suggests at least that when the phobia was excited by the sight or idea of a tower it was due, likewise, to a subconscious process, and that this was one and the same as that which induced the experimental phobia.

2. The phraseology of the script is noticeable. The account is just such as a child might have written. It reads as if the conserved thoughts of a child had awakened and functioned subconsciously.

From this history, so far as given, it is plain that the psychosis in one sense is a recurring antecedent experience or memory, but it is only a partial memory. The whole of the experience does not recur, but only the emotion in association with the ringing of bells. The rest of that experience, viz., the idea of the possible death of her mother with its attendant grief and anguish associated with the visits to the church, the praying for recovery, and, finally, the realization of the fatal ending—all that which originally excited the fear and gave the ringing-of-bells-in-a-tower meaning was conserved as a setting in the unconscious. That the rest of the experience was conserved was shown by the fact that it could be recalled, not only by automatic writing, but, although not in association with the phobia, to conscious memory. From this point of view the fear of bells ringing may be regarded as a recurrence of the original fear—that of her mother's death—now derived from a subconsciously functioning setting. The child was afraid to face her grief and so now the matured adult was also afraid.

From another point of view the ringing of bells may be regarded as standing for, or a symbol of, her mother's death, with which it was so intimately associated, and this symbol awakened the same fear as did originally the idea itself of the death. An object may still be the symbol of another, although the association between the two cannot be recalled. All these memories, involving grief, suffering, self-reproach, bells, and mother, formed an unconscious setting which gave meaning to bells in towers and took part in the functioning to form a psychic whole. The conscious psychosis was first the emergence into consciousness of two elements only, the perception and the effect, and the fear was a reaction to self-reproach, a fear to face self-blame.

A search into the unconscious brought to light a persisting idea that when events in her life happened unfortunately it was due to her fault. It had cropped out again and again in connection with inconsequential as well as consequential matters. She had, for instance, been really unable on many occasions to leave home on pleasure trips for fear lest some accident might happen within the home and, consequently, it would be her fault; and, if away, she was in constant dread of something happening for which she would be to blame. It was not a fear of what might happen—an accident to the children, for example—but that it would be her fault. I have heard her, when some matter of apparently little concern had gone wrong, suddenly exclaim "Was it my fault?" her voice and features

manifesting a degree of emotion almost amounting to terror. When her brother died (still earlier, before her mother's death) she had blamed herself for that death, as later with her mother, on the same religious grounds. This self-reproach for happenings, fancied as due to her fault, has frequently appeared in her dreams. It would take us too far afield to trace the origin and psychogenesis of this idea. Suffice to say, it can be followed back to early childhood when she was five or six years of age. She was a lonely, unhappy child. She thought herself ugly and unattractive and disliked, and that so it always would be through life, and it was all her fault because she was ugly, as she thought. The instinct of self-abasement or negative self-feeling dominated the personality as the most insistent instinct, and, from its intensity within, the self-regarding sentiment formed a sentiment of self-depreciation. She wanted to be liked, and believed it to be her own fault that, as she fancied, she was not and never would be, and reproached herself accordingly. This sentiment of self-depreciation, with its impulse to render self-reproach, has persisted, as with many people, all her life, and has been fostered by unwise and thoughtless domestic criticism.

Returning to the phobia for bells, in the light of all these facts the patient's belief that her mother's death was her fault and the consequent self-reproach were obviously only a particular concrete example of a lifelong emotional tendency, originating in the experiences of childhood, to blame herself; and this tendency was the striving to express itself of the instinct of self-abasement (with the emotion of self-subjection), which, incorporated within the self-regarding sentiment, was so intensely cultivated and had played so large a part in her life. Indeed, this instinct had almost dominated her self-regarding sentiment and had given rise time and again to self-reproach for accidental happenings. It now specifically determined her attitude of mind toward the series of events which led up to the fatal climax and determined her judgment of self-condemnation and self-reproach. These last most probably received increased emotional force from the large number of roots in painful associations of antecedent experiences, particularly of childhood, in which the self-regarding sentiment, self-debasement, and self-reproaches were incorporated. Nevertheless, the fear was of a particular concrete self-reproach. The general tendency was of practical consequence only so far as it explained the particular point of view and might induce other self-reproaches.

As a general summary of this study it would appear that we can postulate a larger setting to the phobia than the grief-inspiring experiences attending her mother's death. The unconscious complex included the belief that she was to blame and the sentiment of self-reproach, and the whole gave a fuller meaning to the ringing of bells in a tower. The fear, besides being a recurring association, was also a reaction to the subconsciously excited setting of a fancied truth or self-accusation. Although excited by towers and steeples, the fear was really of self-reproach. Towers, steeples, and bells not only, in a sense, symbolized her mother's death, but her own fancied fault. It was in this sense and for this reason that she dared not face such objects.

The conscious and the unconscious formed a psychic whole.

Now, in reaching these conclusions see how far we have traveled: Starting with an ostensible phobia for towers, we find it is more correctly one of ringing of bells, but without conscious association; then we reach a childhood's tragedy; then a self-reproach on religious grounds; then a belief in a fault of childhood's behavior culminating in a lifelong self-reproach—the casual factor and, psychologically, the true object of the phobia; and between this last self-reproach and the phobia no conscious association.

511 EAST ELEVENTH STREET.

SOME PRACTICAL POINTS IN ENDOCRINOLOGY, WITH ILLUSTRATIVE CASES.*

BY J. W. TORBETT, B.S., M.D.,

MARLIN, TEXAS.

I SHALL make no apologies for selecting this subject, because its importance will be vouched for by any one who has even occasionally made a correct diagnosis and seen the remarkable results that follow the use of the proper gland therapy. I believe the internal secretions are, in a great measure, mutually interdependent upon each other, and hence are recognized by correlated group symptoms of disharmony rather than symptoms of one gland alone. As editor of the department of Gland and Serum Therapy in the *American Journal of Electrotherapeutics and Radiology* and as a member of the Association for the Study of the Internal Secretions the writer has had occasion to review the Bulletin, *Endocrinology*, in its original articles and abstract department, too, for the past four years. These articles are so numerous and the views are so diverse that I shall in this article attempt to simplify and classify some of the practical points that have been verified in my own experience, rather than wander off into the hazy field of scientific speculation. While perfect harmony between all the endocrine glands is best for perfect health, Kaplan and also Fraenkel have recently claimed that many persons may have a dominating influence of one or more glands as shown by their physical appearance without affecting their health badly.

Prof. Emile Sergent of Paris claims that hypoadrenia is one of the most common of the endocrine dysfunctions in tuberculosis, while Harrower of California says that it is present in the neurasthenic and postinfluenza toxemias, so numerous now among our chronic cases. Steinach's recent claims in making old mice and guinea pigs young by transplanting the respective young sexual glands and even changing entirely the sex of the animal by using the opposite sex glands show the possibilities of the subject.

Dysfunction of the thyroid and gonads may cause many neurasthenic symptoms but the general tired condition of asthenia, loss of "pep," mental and physical inability to work, the white line of Sergent on the skin with low blood pressure, following influenza and other chronic diseases and focal infections, come from the exhausted adrenals.

*Read before the Central Texas and Seventh District Medical Societies.

Prof. Cannon has shown that fear, rage, anger, and pain and perhaps worry act upon the adrenals similarly to the toxins of disease, nicotine, etc., in exhausting the function of the glands. Since the adrenin combined with the thyroxin greatly govern the process of oxidation, the exhausted condition of these glands tends to metabolic laziness and cellular insufficiency. The cells are unable to eliminate their own waste products which are mostly acid in character, hence a tendency to acidosis occurs with a greatly reduced output of urea. Strychnine, as pointed out by Stewart and Ragoff, perhaps stimulates the adrenals more than any drug, but it is very injurious in these exhausted conditions which have come about from overstimulation already. Small doses of adrenin, thyroid, and if constipation be present, pituitrin, often assist such patients to a rapid recovery. Garretson says the hypoadrenia is apt to have tingling, flashes, and paresthesia with a tendency to hyperchlorhydria, hypertension, diphtheria, hernia, and varicocele.

The adrenals maintain the tonus of the sympathetic supplying the longitudinal fibers of the bowel muscles, while the pituitrin controls the terminal vagus supplying the circular fibers of the bowels, which gives a better understanding of constipation and diarrhea. The hypothyroid person is one slow, sluggish, and with subnormal temperature, with a dry, scaly, or parchment-like skin that sweats but little except in the palms, thin outer end of eyebrows, lowered tolerance of meats and cold. The hyperthyroid has a thin, clear skin, small white teeth, a tendency to elevation of temperature and pulse rate, to sweat easily, to be nervous, hysterical or hypochondriac, and acquire intestinal and cardiovascular disorders. The pituitrin persons are prone to diseases of periodicity like malaria and syphilis, their teeth are usually well separated; they also may have thick hair on unusual parts, like the adrenotrop; while a hypopituitarism of the posterior lobe persons may have increased carbohydrate tolerance with increased fat in hips and flanks, with decreased pubic hair, etc.

CASE I.—One of my first cases of endocrine dysfunction was a lady from McGregor several years ago who had been an invalid some years with a severe form of stomach trouble which is sometimes called Richmann's disease. She would vomit large quantities of greenish fluid and have severe pains in the lower abdomen near the bladder and be so nervous with vertical headaches she could not bear any noise. These spells would come, she said, every three or four weeks and last for about five or six days. The regularity of the trouble and the fact she was only about thirty years old and with both ovaries removed some time ago gave me the suggestion that she might have a surgical menopause as the cause of her nervous and gastric symptoms. The use of the ovarian substance with a good balanced ration soon restored the lady to fine health though she kept up the tablets for several months just before the regular time she expected the return of the symptoms with entire prevention of same. She was in good health until the meningitis epidemic when I have since learned she succumbed to an attack of that disease.

CASE II.—Mrs. R. from Snyder, Texas, who had been troubled for several months with a severe form of arthritis. She had very little fever, no decided leucocytosis, had a very dry, shiny skin, slow pulse, diminished periods, poor tolerance of cold and meats, with a pronounced atonic constipation. No other focus for the infection being found her case was diagnosed as a low grade of infectious arthritis due to the intestinal stasis and its consequent autotoxemia,

giving in turn an hepatic insufficiency and hypothyroidism due to the overworked and exhausted condition of the detoxicating functions of those two glands. She was given a course of baths and saline laxatives for general elimination, massage and high frequency electricity for their local, and static electricity for its general effect upon the nervous system and circulation, with no meat but plenty of milk which Lorand says is the best food stimulant of the thyroid, with also a generous supply of greens, lettuce or celery, orange juice, and potatoes which contain iron for building the hemoglobin and which McGarrison has recently shown contain the antiscorbutic vitamins that best promote the proper function of the adrenals. The adrenals are now known to be usually deficient in cases of hypothyroidism. Loss of "pep," low blood pressure, the Sergeant line, diminished muscular heart tone, in fact the usual neuroathenic fatigue syndrome, are the usual symptoms of hypoadrenia. Small doses of thyroid extract alternately with the syrup of iodide of iron were also given for six months at least, when the bowels were again normal, the skin soft and moist, the arthritis entirely gone, periods regular and later she had a fine baby.

CASE III.—Dr. B. of Alabama, age thirty-five, had always been healthy until last year when he had a very severe attack of influenza from which he never entirely recovered. He gradually became slower in his movements, his face was bloated, especially after eating meats, of which he was a large consumer. He could not talk rapidly and would very frequently get his tongue tangled so that he could with difficulty carry on a conversation. He had been examined by numerous physicians for every kind of focal infection and had a renal function test but no satisfactory diagnosis nor results from treatment. Our laboratory tests of the blood, urine, etc., showed nothing especially wrong, neither did regular physical, eye, ear, nose, throat, and retinoscopic examinations. Our diagnosis of hypothyroid and hypoadrenia following a post-influenza toxemia, was based upon the slowed speech and pulse with no signs of brain tumor, the dry skin and hair with the outer portion of the eyebrows fallen out, a diminished tolerance for meats and also cold. Breischauer showed several years ago that dogs with the thyroid removed could live on bread and milk but died soon if fed on meats. His easy fatigue, loss of "pep," low blood pressure, and the Sergeant white line showed the hypoadrenia. The mixed gland tablets with one-grain tablets of thyroid extract added after a few days restored him so that in one week he could talk without getting his tongue tangled and he writes he is now back on the job active as ever. The mixed glands formula is: thymus gland gr. 2, thyroid gland gr. 1/5, pituitary gr. 1/2, suprarenal gland gr. 1/4, didymin gr. 1/2, and cerebrin gr. 1/2. He now writes a good letter and does not leave out any words as he once did. He was, of course, put on the diet mentioned above but had to return home at the end of one week and did not get the other lines of treatment as given the other patients. His case was one that had not advanced so far and hence was not so easily recognized but was much more amenable to treatment. The grouping of small symptoms is the method for the early diagnosis and the search for pluriglandular disharmony, and not one gland deficiency, the means of greatest success.

CASE IV.—Mrs. L., age about twenty, very active and intelligent, married about two years with no pregnancies, had very profuse and continuous periods that refused to be controlled by any local or systemic remedies, and even returned after a few x-ray treatments had reduced the flow. The physical examination disclosed nothing but a large soft uterus with very small, flabby breasts. The administration of mammary gland extract three times daily soon regulated the flow and by taking the tablets at the regular period since then she has become entirely normal.

Such cases in young girls with sweethearts who hug and kiss them much, giving hyperactive ovaries, should have the adrenin or pituitrin added to the mammary gland treatment, according to which one the symptoms call for.

Many married and also many young girls are not promptly relieved of annoying nervous symptoms because of the difficulty in determining their gland disharmony. These glandular dysfunctions are frequently hereditary as a careful family history will disclose. Rhythmical regularity is a pituitrin function and irregularity its dysfunction. The cystic ovary with its varied contributory causes and many unpleasant symptoms of pain, nervousness, anemia, and mental unrest, is a trouble that demands our skill to give relief. Several cases during the past year with pain, nausea, nervousness, and even some so toxic as to have fever at that time have been relieved entirely by the whole ovarian substance with cacodylate of soda or iron intravenously, tincture of iodine and menthol painted locally for pain in conjunction with the generous full vitamins, fresh fruit, vegetable, and milk diet. Best results, of course, always follow the early recognition of the causative factors of the glandular dysfunction. S. W. Bandler, writing in the *Medical Clinics of North America*, ii, 4, 236, shows that the ovarian, thyroid, suprarenal, and posterior-pituitary glands support the genitalia, while the thymus, mammary, anterior-pituitary, and placental depress them.

Dr. Walter Timme has an article in the same issue on the new pluriglandular compensatory syndrome characterized by severe spells of intratemporal or pituitary headaches, blood sugar disturbances, intense fatigability, temperamental unfitness, irregular or abnormal skeletal or bone development, and unnatural spells of drowsiness. Such cases, he says, are relieved by being fed the whole pituitary body, from one to four grains every second day.

Perhaps the most difficult cases to recognize are those who in early or middle life have had one or more hyperactive glands that later were partially removed by surgery or become exhausted and atrophied from excessive use. Focal or systemic infections, intestinal stasis and its toxemias, a one-sided diet with too few vitamins, worry, grief, shock, and excessive use of a gland are the principal causative factors giving disharmony.

The fresh gland dose is usually about five times that of the desiccated gland and can be best given in institutions by being prepared in the diet kitchen, being ground up with bread or rice puddings and afterwards slightly toasted. It is our intention to further follow the results of such feeding in the diet kitchen of our institution in chronic cases.

In conclusion, I wish to say that endocrinology offers a large and useful field for study and discovery, but it behooves us to use caution to temper our judgment and enthusiasm, as thyroid extract, pituitrin, and adrenin are formidable weapons of great danger when not carefully and correctly used.

TORRETT SANATORIUM.

Another Reflex Discovered.—Mavinesco and Radovici, in a case of amyotrophic lateral sclerosis with marked spasticity, found that stimulation of the thenar eminence produced a slow contraction of the mental group of muscles on the corresponding side of the chin, which was thus retracted. This led them to examine 300 persons whose nervous systems were apparently normal. The reflex was found to be present in about 50 per cent. The muscular contraction in the normal subject, however, is sharp and brief, while if the pyramidal tracts are diseased, the response is sluggish and prolonged.—*The Medical Press*.

VOLVULUS OF THE INTESTINE.

REPORT OF A CASE WITH SUCCESSFUL RESECTION OF TWENTY-EIGHT INCHES OF GANGRENOUS SMALL INTESTINE.*

By HARRY COHEN, M.D.,

NEW YORK.

ATTENDING SURGEON PEOPLES' HOSPITAL.

ACUTE intestinal obstruction is always of interest to the surgeon, as is one of its causes, volvulus, a brief description of which follows.

Definition.—Volvulus consists in the twisting of a loop of intestine on its axis so as to obstruct its lumen and vascular supply. This definition (Bryant¹) describes the conditions briefly yet fully.

Incidence.—It is one of the least frequent of the causes of intestinal obstruction. The relative frequency of this disease may be judged by the report of Gibson² that in one thousand operations for intestinal obstruction, volvulus occurred one hundred and twenty-one times. Commenting on this, Erdman³ believed the number one-hundred and twenty-one much too large proportionately, since in Gibson's cases foreign references were frequently drawn upon. Deaver⁴ reports two hundred and seventy-six consecutive cases of acute intestinal obstruction admitted to the German Hospital in the ten years ending with 1913. In this series there were only five cases of volvulus.

Age and Sex.—Volvulus may occur at any age but is most frequent from forty to sixty years. Manson⁵ reported a case in an infant. As to sex, it is much more prevalent in the male, in the proportion of two to one (Erdman); to four to one (Bryant). In women, it usually occurs in those who have borne many children (Tillmanns⁶).

Etiology.—The etiology may be classified under three subdivisions: (1) Predisposing causes, (2) requisites, (3) exciting causes.

1. Among the predisposing causes may be mentioned Meckel's diverticulum, appendicitis, apertures in the peritoneum and mesentery, a relaxed condition of the abdomen and of the intestines, and an elongated mesentery (Mekechnie⁷).

2. Requisites, as stated by Power,⁸ are three, (a) a loop of bowel lying less securely packed than usual in the peritoneal cavity; (b) loaded bowel; (c) irregular peristalsis.

3. Exciting causes: (a) Contusions of the intestines; (b) Peristaltic movement of the intestine when it is unequally filled (Tillmanns⁹); (c) bands and adhesions; these are placed among the exciting causes, because they are the most frequent. (Lillienthal¹⁰ and others); (d) ascaris lumbricoides (Heiser¹¹); (e) adenomatous polyp (Manson).

Location of Volvulus.—The location of volvulus is as follows: Most frequently it is found in the sigmoid in about one-half of the cases; next in the cecum and last in the small intestines (Brewer¹²). Other parts of the intestinal tract may become the seat of a volvulus as a Meckel's diverticulum, cecum and appendix (Edwards¹³), entire colon and sigmoid (Kerr¹⁴ and Eisendrath¹⁵), hour-glass stomach (Barbacci¹⁶), and the total intestines (Ombiedanne¹⁷).

*Case presented at Clinical Society Meeting, Peoples Hospital, April 14, 1920.

Symptoms.—The symptoms of volvulus resemble those of intestinal obstruction in general with some modifications. Volvulus, like other forms of intestinal obstruction, may be either acute or chronic. Bloodgood² reports a case of chronic volvulus with thirty-two attacks extending over a period of sixteen years. Ombiedanne's case was also chronic and probably congenital. Hirschsprung's disease (megacolon) may be a result of this condition in a congenital form. Of especial interest are those of the acute form. They depend considerably upon the location. Acute volvulus is usually ushered in with an acute sharp pain in the abdomen. This is followed in several hours by distention, which is usually high up in the abdomen. Shock, an early symptom in other forms of intestinal obstructions, usually appears late in this disease, frequently not before several days. There is often a visible mass situated over the site of the volvulus and peristalsis radiating toward the mass may be seen. Vomiting is usually a very late symptom and may not be present at all. If present, as the case progresses it may become fecal in character. Obstipation is the rule but even this may appear late owing to accumulations in the colon and rectum. Tenderness over the mass is also an early sign. The temperature and pulse will vary depending upon the condition of the intestines and complications such as gangrene of the intestines or peritonitis. Mucus and blood in the stools present in other forms of intestinal obstructions do not occur here. Flatus is not passed.

Prognosis.—The prognosis depends on many factors. In the chronic form, the prognosis is good, as the volvulus rarely goes on to strangulation. In the acute form the prognosis depends upon (1) early diagnosis, (2) time of operation, (3) condition of the intestine, (4) presence of complications, (5) necessity of resection, (6) amount of resection, (7) location of the volvulus, (8) general condition of the patient.

Gibson gives the mortality as 70 per cent. when the small intestine is involved and as 46 per cent. when the large. Erdman quotes Gibson to show the seriousness of volvulus when it affects the small intestine. "Only one case in the entire list recorded was successful after resection of the small intestine was performed. This case was operated upon the second day, one hundred and twenty-seven centimeters being removed." Power states that in his hospital from 1899 to 1915 there were twenty-five cases of volvulus with twenty-one deaths. Erdman resected twelve inches of small intestines in one case with recovery. In Deaver's cases, two out of five died.

Treatment.—The treatment, of course, is early operation and finding and releasing the cause. Bands, adhesions, etc., when discovered are divided, then the volvulus is untwisted, emptied of its gas, and a rectal tube is inserted. Other surgical procedures, such as resection, etc., will depend upon what complications are found.

CASE.—Mrs. Y. W., aged 62, widow, consulted me March 3, 1920, complaining of pain in the epigastrium and abdomen. Her previous and personal history were negative except that for six years past she had suffered with a rodent ulcer of the forehead, for which she was treated at the Skin and Cancer Hospital. She apparently has been cured of this ulcer, as only a

minute trace is still visible. Her present history dates back several months, her chief complaint being pain in the epigastrium and umbilical regions. There is no history of vomiting, hematemesis, or jaundice. Constipation was a prominent symptom, cathartics being constantly necessary. She also complained of nausea, anorexia, headaches, and general weakness. There was no other history. Physical examination showed her poorly nourished and emaciated. Heart and lungs were negative. On examination of the abdomen, the liver was found to be slightly tender and enlarged to about two fingers' breadth below the free costal margin. There was also tenderness in the epigastrium. No tenderness nor masses were felt elsewhere in the abdomen. She also had a right femoral and left inguinal hernia. While undergoing a roentgenographical examination, immediately after the ingestion of the barium meal, she developed severe colicky pains in the abdomen as a result of which the examination could not be made nor could any plates be taken. The abdominal pains reappeared several hours later and progressively increased in severity. This suffering continued through the night. A local physician had to administer three-quarters of a grain of morphine hypodermically. She vomited frequently, but the matter was not fecal in character. She passed no feces nor flatus. This occurred on March 4. On March 5 I was called in to see her. Her pain had been only slightly relieved by the morphine. The vomiting continued. No flatus had been passed. She was in collapse; the pulse was of poor quality, feeble, and rapid; the temperature 99° F. On examination the abdomen was found to be distended, the distention being in two distinct places—high up in the abdomen and in the appendix region. In the latter location a rather large mass was visible and easily palpable. Palpation, even in her semiconscious condition, caused her pain. The presence of intestinal obstruction was evident, with a probability of volvulus. She was immediately removed to the Peoples Hospital and operated upon by me. Surgical interference took place about twenty-two hours after the initial attack of pain.

An incision was made over the mass and through the right rectus about the umbilical region. On opening the peritoneum a very large amount of bloody fluid escaped. The first impression on opening the peritoneum resembled that of a ruptured ectopic pregnancy. The bloody fluid in this case, however, did not clot. On exploration, a large, very heavy mass, consisting of a double coil of gangrenous small intestine was seen. The black color of this mass contrasted markedly with the remainder of the small intestine, which was very pale. This gangrenous intestine was found coiled upon itself from right to left about one hundred and eighty degrees. A band of adhesion constricted it at the base. The mass consisted of ileum about one foot away from the ileocecal junction. The band was immediately cut, the coils untwisted, intestinal clamps were applied, and the entire mass was resected. An end-to-end anastomosis (McGrath method) was then performed. The peritoneal cavity was flushed out with hot saline solution, a large quantity of which was allowed to remain. The abdomen was then closed up. The entire operation took thirty minutes; gas-oxygen anesthesia was used. The patient made an uninterrupted recovery, leaving the hospital in two and a half weeks. There was nothing special in the after treatment. The excised coils of ileum measured twenty-eight inches and were very heavy. There was no apparent cause for the original band, as there had been no previous operation. The betterment in her condition was noted from the moment she was through with the operation, as immediately there was a marked improvement in her pulse.

Conclusions.—1. Volvulus of the small intestines is of rare occurrence.

2. The prognosis is grave and depends upon early diagnosis and early operation.

I am indebted to Dr. Sol. Rottenberg for assistance.

64 EAST THIRD STREET.

ANESTHESIA IN DENTAL SURGERY.

BY M. ECKER, D.D.S.,

NEW YORK.

PAIN is the usual outstanding symptom of one who seeks relief from a throbbing tooth. Not only so, but this pain, however slight, is a warning of trouble ahead, unless the offending member is removed or otherwise treated. What a relief and gratification for the patient who, entering a modern dentist's office, finds that not only is the pain relieved, but a new sensation, pleasurable in the extreme, is experienced during the extraction! Taking advantage of the synergistic effect of the safest and most powerful analgesics and anesthetics in our pharmacopœia, he does not realize that evolution in Slumberland is still in progress, and that the last word is yet to be said concerning this most important subject; he merely knows that he has been relieved of suffering, without additional pain, and that he is able to walk from the operating theater without nausea, vomiting, or headache.

While it is generally conceded that a physician, Crawford W. Long of Georgia, was the first to use ether to deaden the pain of a surgical operation, the world is indebted to a dentist, William T. G. Morton of Massachusetts, for the first public demonstration of any anesthetic. Another dentist, Horace Wells, is credited with the discovery of the anesthetic properties of nitrous oxide, but his unfortunate failure in an attempted public demonstration of the use of the gas apparently delayed its practical application, and little was heard of it until more than twenty years later, when Colton recorded twenty thousand administrations without an accident. Up to this time (1867) little differentiation was made between cyanosis and anesthesia, and with a few dentists and doctors this is true even to-day. In 1868 Andrews of Chicago, reported the use of a mixture of nitrous oxide and oxygen, stating that he had obtained a more satisfactory form of anesthesia with the combination than with nitrous oxide alone.

Flourens first mentioned ethyl chloride as an anesthetic in 1847, but it was not used for this purpose

until 1895, since which time it has gained rapidly in favor. While its use by dentists in the United States is comparatively limited, it is extensive in South America and in England. The after-effects of ethyl chloride do not begin to compare with those from nitrous oxide. There is, however, one very great advantage in using ethyl chloride, namely, that there is an analgesic stage, immediately before the patient loses consciousness and also immediately after the return of consciousness, during which the dentist can work. This analgesic stage does not exist with nitrous oxide, given alone or with oxygen.

The object of this paper is to direct attention to the possibilities of combining the good effects of nitrous oxide and ethyl chloride in attempting to modify the anesthetic in such a way that the analgesic stages are imparted to the nitrous oxide and oxygen anesthesia, while the nausea and vomiting, and the possibility of collapse, that sometimes follow ethyl chloride alone, are eliminated. Like all methods and techniques, this latest method is a product of evolution which only now, in the last few thousands of cases, is accomplishing what we were striving for at the outset.

It may be stated here that, while nitrous oxide-oxygen alone is sufficient for the majority of cases, there are exceptional cases in which it is far from satisfactory. It was with the hope of ironing out the exceptions, so to speak, and of making the procedure more satisfactory from the operator's standpoint, that we determined to change our technique. In doing so we have been enabled to take advantage of certain important research work now being conducted in this city. At the suggestion of Dr. J. T. Gwathmey, at first we passed the nitrous oxide and oxygen over, not through, a mixture called anæsthol, which is supposed to combine in a stable chemical union, roughly, about 17 per cent. of ethyl chloride, 35 per cent. of chloroform, and 47 per cent. of ether. We found this chemical union to be very unstable. When freshly poured in, it acted better than when almost used up. The ethyl chloride is given off first, giving the combination of nitrous oxide, ethyl chloride, and oxygen; later, as the ethyl chloride is exhausted, there is a combination of nitrous oxide, ether and chloroform, with possibly small traces of ethyl chloride; still later, as we get near the bottom of the container, there is a mixture of nitrous oxide and chloroform and small amounts of ether and ethyl chloride. With this last mixture the writer had one case of slight chloroform poisoning, as indicated by pallor around the margin of the lips, and a tendency to vomit.

The explanation of the giving off of the mixtures in the order stated is to be found in the specific gravity of the mixtures which, compared with air, is as follows: One volume at 0° C. and 760 mm. barometric pressure: ethyl chloride, 2.22; ethyl ether, 2.56; chloroform, 4.21. The ethyl chloride being the lightest, is given off first, the ether next, and the chloroform last.

With the mixture freshly prepared, there is less tendency toward vomiting—the patient receives more of the nitrous oxide, ethyl chloride, and oxygen, and small traces of the other ingredients. When the container is about half empty there seems to be more of the ether effect, with an occasional tendency toward retching; and, later, when

two-thirds of the mixture is used up, the chloroform effect is apparent, and there is not so good an effect from the operator's standpoint as when the mixture is freshly poured in.

Knowing that different anesthetics and narcotics affect different parts of the central nervous system, and believing thoroughly in the theory of the synergistic action of drugs, I commenced using a fifty per cent. mixture of paraldehyde and anæsthol, and obtained a slightly better effect than when anæsthol was used alone. Paraldehyde is conceded to be one of the safest drugs in the pharmacopœia, and while the amount used of any of the drugs named, with any one patient, is far below the minimum physiological dose, yet the resultant narcotic picture, as reflected in the patient, more than justifies the continuation of their use.

At first I used Cotton-process ether, manufactured by the Du Pont Manufacturing Company, which is supposed to eliminate in very great measure the disagreeable effects of ether as commonly manufactured and sold in the United States. It is claimed to contain certain amounts of ethylene gas. Passing the nitrous oxide and oxygen over the Cotton ether, this combination was administered in forty-eight cases. In eight cases there was nausea, and in two cases there was vomiting. The last two patients were quite sick, necessitating lying down for an hour. The anesthetics were perfect, more satisfactory than with the gases alone; but on account of the after-effects I felt, and still feel, that this combination has no place in the general routine of oral surgery.

The next combination tried was nitrous oxide, oxygen, and anæsthol, which was employed in sixty-two cases. In six of these cases there was nausea, and in a few cases there was slight cyanosis. I felt that this combination had to be improved as regards the after-effects. The anesthesia was quite as good as with the Cotton-process ether, but the patient returned to a normal condition more rapidly than with the ether.

The next combination was with the gases passed over paraldehyde, and was used in one hundred and thirty cases. Very few changes in the anesthesia were noted, but the patients found it not unpleasant to take, and they were less hysterical afterward. There was no nausea, vomiting, or headache in this series. It was decided, therefore, to retain the paraldehyde in our armamentarium, with whatever other agents we might decide to use.

The next combination was a fifty per cent. mixture of paraldehyde and anæsthol over which the gases were passed. Over twelve thousand administrations have been given with this combination. The anesthesia is better than with any of the other combinations mentioned. First, the stage of excitement, while rarely seen with any of the combinations mentioned, is not infrequent with nitrous oxide and oxygen alone. This was practically eliminated with the last mixture. Second, the full surgical stage, *i. e.* for tooth extraction, is more rapidly induced, averaging about one minute and fifteen seconds. The stage of anesthesia in which we operate is everything that could be desired, and lasts two minutes and longer, after the mask is removed. Although the eye reflex returns to normal, an analgesic stage is always present, and this

is determined by curetting about the socket of the tooth extracted. The relaxation is more complete than heretofore. Whereas formerly we used a holding strap for athletes and alcoholics, who usually resist nitrous oxide and oxygen alone, we have now dispensed with this entirely. In other words, we have ironed out the exceptional patient. Erotic and other dreams are conspicuous by their absence. It may be noted in passing that hallucinations under nitrous oxide and nitrous oxide-oxygen quite frequently occur with the highly neurotic patient. The tension upon the operator at the end of a busy day is markedly less with the combination now used than with nitrous oxide-oxygen alone. For operations in which I formerly resorted to the use of novocain, such as the drilling out of a root or a slightly unerupted tooth, I now use this combination. Ten drops of anæsthol is the average amount used with each patient.

To summarize: (1) The operation is absolutely painless, as evidenced by the quiet state of the patient during operation, no unpleasant reflexes appearing at any time. The narcosis seems to be more acceptable to the patient than that from the gases alone, as evidenced by the facial expression. Rigidity is markedly lessened. Hysterical outbursts are now rare. The patient leaves the room without assistance and in a quiescent state. (2) This method is applicable in general surgery, in hospitals and out-patient clinics where a short but safe anesthesia is required.

147 FOURTH AVENUE.

RECTAL CONSTIPATION: ITS SIGNIFICANCE AND TREATMENT.

BY E. JAY CLEMONS, M.D.

LOS ANGELES, CAL.

THE five common symptoms complained of by sufferers from anorectal troubles are constipation, diarrhea, pruritus, protrusion, and discharge. Of these, rectal constipation is the most frequent, in fact it is the commonest complaint from which man suffers. Of all the distresses that afflict man none compares with the discomfort of the effects of rectal constipation.

Rectal constipation due to downward displacement of anatomical structures constituting the anorectal line, such as hypertrophied anal papillæ anal cryptitis, complicated anal fissures, so-called "sentinel pile," prolapsed polypi, internal hemorrhoids (past the second degree), mixed hemorrhoids, and rectal prolapse is here considered; no reference being made to obstructive rectal constipation, such as is caused by pressure of adjacent organs, angulations, constrictions, adhesions, rectal valve hypertrophies, or new growths.

Patients suffering from this form of constipation are neurasthenics and hypochondriacs and are also sufferers from indigestion and palpitation. This is owing to the fact that tissues supplied by the vegetative (sympathetic) nerves have become displaced in such a manner as to come in contact with and to remain within the grasp of the external anal sphincter muscles, thereby resulting in spastic constipation because of the direct and indirect interference with peristalsis and defecation.

Spastic constipation causes an imbalance of the normal intraabdominal gaseous pressure, resulting in dilatation of the stomach. This dilatation of the stomach results in the viscera becoming dependent upon the fixed portions of the alimentary canal for support, thus inducing gastroenteroptosis. This condition is accompanied by bodily derangement which varies from a slight indisposition to a most profound autointoxication. This is because such a complex condition of affairs deranges digestion, assimilation, elimination, and oxygenation causing dyspepsia, malnutrition, and overloading of the tissues of the body with waste products.

The significance of rectal constipation is therefore of the greatest importance as the effects of this condition are a most vital factor in the health, happiness, contentment, and wellbeing of mankind because of the fact that no man can enjoy health, happiness, contentment, and wellbeing who suffers from the effects of rectal constipation.

The object to be accomplished in the treatment of this form of constipation is the surgical removal of the offending pathological tissue in a manner so as not to interfere with the normal nerve supply and not to have resulting post-operative tags and contractures, at the same time reconstruct the parts in such a manner as to prevent tissue supplied by vegetative nerves from again becoming within the grasp of external anal sphincter muscles. This object is best accomplished under local infiltration anesthesia using one-thirty-second of one per cent. aqueous solution of procaine hydrochloride supplemented by one to 50,000 epinephrin hydrochloride for the purpose of keeping the parts ischemic, decreasing rapidity of anesthetic drug absorption and prolonging anesthesia.

The patient is instructed not to interfere with his daily routine till the morning set for the operation when he is to have dry toast and black coffee for breakfast before entering the hospital. After going to bed the assistant shaves the perineal region and administers a two quart plain enema. He is then placed, after expelling the enema, upon the operating table on his left side with knees flexed upon abdomen, separated by pillows. The parts are then prepared for the operation.

The operation is begun by applying the cotton tipped end of an applicator, which has been dipped in phenol, to a point upon the skin surface one-half inch to the left of the anus. This is for the purpose of anesthetizing the skin and marking the place for the insertion of the needle. After waiting till this spot has turned white and the patient informs one that the burning sensation has ceased you then insert a fine hypodermic needle attached to a half ounce metal syringe, loaded with the anesthetic solution, into the loose subcutaneous tissue by puncturing the skin at a point in the center of the carbolyzed area. Inject this solution very slowly. At the first indication of pain stop and wait till the pain ceases, then inject a little more solution, so slowly that you do not hurt the patient or blanch the parts. Upon thoroughly distending the tissues from this puncture you have prolapsed the pathology and brought out the ano-rectal line, at the same time the solution has not passed the median raphe. Now insert the needle of a ligature carrier threaded with number two ten-day chromic catgut,

beginning a quarter of an inch in front of the posterior median raphe at the level of the ano-rectal line, pass deeply, penetrating the deep fascia, and come out a quarter of an inch behind the anterior raphe at the level of the ano-rectal line. Remove the ligature carrier. Grasp the distended structures with vulsellum forceps and, while making traction, tie the ligature taut enough to strangle all tissue within its grasp. The skin is then cut up to the ligature, beginning at a point approximately one inch from the anus. The same procedure is repeated upon the right side, thus leaving two strips of undisturbed tissue through the anal canal while the rectal mucosa is drawn down, strangulated and anchored laterally by the two ligatures whose tension approximates the skin edges, leaving no raw surfaces.

The parts are dressed daily with gauze smeared with sterile petrolatum. The first twenty-four hours the patient sips six ounces of water every four hours at fifteen minute intervals, thus keeping up peristalsis, causing gas to pass freely per anus. When gas passes the urine is voided without difficulty and the patient does not suffer from pain. Peristalsis and nutrition are maintained the next seventy-two hours by four ounces of beef broth and four ounces of sweet whey given every four hours, the broth to be drunk hot and the whey to be sipped every fifteen minutes at the rate of an ounce an hour. On the fourth day an enema is administered, the patient put on a full diet and encouraged to go about his business. He reports weekly till the parts heal and a seven-eighths inch anal dilator can be passed without injury.

In conclusion it may be said that this treatment alleviates one of the most distressing afflictions from which man suffers with the minimum risk and discomfort.

605 HOLLINGSWORTH BUILDING.

Medicolegal Notes.

Identification of X-ray Pictures Admitted in Evidence.—In an action for damages for a broken leg caused by being run down by an automobile, objection was made to the introduction in evidence of an x-ray picture of the plaintiff's broken leg, made while he was being treated for his injuries at a hospital. The plaintiff testified that he was exposed to the x-ray machine in two different ways, and that the next day the doctor presented him with these pictures, which showed the leg as being broken. It was held that the plaintiff's testimony sufficiently identified the pictures for admission in evidence.—*Mankin v. Bartley, C. C. A., 266 Fed. 466.*

Period of Employer's Liability for Medical Services Under Workmen's Compensation Act.—The Illinois Workmen's Compensation Act provides that "the employer shall provide necessary first aid, medical, surgical and hospital services; also medical, surgical and hospital services for a period not longer than eight weeks, not to exceed \$200. It is held that the Legislature did not intend that the eight weeks should necessarily be confined to the time immediately following the injury, since it frequently occurs that the results of the injury do not develop to such an extent as to require medical, surgical, or hospital services for a considerable time after the injury is received; and to hold that such services are to be supplied only within the first eight weeks following the injury would, in many instances, limit them to but a part of eight weeks, and in other cases prevent recovery for such services altogether.—*Chicago-Sandoval Coal Co. v. Industrial Commission, 294 Ill. 351, 128 N. E. 567.*

THE ETIOLOGY AND PATHOLOGY OF INFECTIOUS PULMONARY EDEMAS.

THE etiology of infectious pulmonary edema is extremely variable, but usually is due either to the bacillus of tuberculosis or to the pneumococcus. The former organism is more prone to produce satellite infectious edema, and perhaps also serous inflammatory tuberculosis, without any particular characteristic, specific or otherwise. The pneumococcus, while contributing its part to the production of satellite edemas is, so to speak, the causal agent of *autonomous* infectious edemas. It is interesting to note that the pneumococcus, which is the primordial factor of chloride retention is, at the same time, at least as far as the lungs are concerned, the hydropigenous bacterium *par excellence*. The elective preservation of the vitality of the pneumococcus on a defibrinated blood medium—made according to the procedure of Gilbert and Fournier—constitutes the rigorous experimental reproduction of prolonged pneumococcemias vegetating in the edema.

The polymorphism of the pneumococcal manifestations is to be particularly insisted on. The pneumococcus is, in point of fact, the causal agent *par excellence* of the four great infectious pulmonary syndromes of a nonspecific nature, resulting from the afflux of the constitutive elements of the blood into the infected territory, as follows: Firstly, fibrin. The fibrinous reaction, the type of which is frank acute lobar pneumonia, with the pneumococcus as its almost exclusive etiological factor. Secondly, the red blood corpuscles. A simple congestive reaction, whose classical type is Woillez's congestive type, a simple attenuated abortive pneumonia. Thirdly, the leucocytes, with the leucocytic reaction, the suppurative syndrome of collected abscesses in the lung or of bronchopneumonia, both processes having an equally frequent pneumococcal etiology. Fourthly, the serum, with the serous reaction. This is the syndrome of infectious edemas of the lung, which usually are nothing less than prolonged pneumococcemias.

Macroscopically, there is a gelatinous subpleural edema, preferably occupying certain edematous areas, such as the edges of the lung, the hilum and fissures; the edema of the parenchyma with tur-

gescence of the lung, which is easily depressed in a cup-shaped hollow with the finger, floating on water, and on section giving issue to albuminous serosity, aerated and reddish in color and occasionally streaked with fine purulent lines.

Microscopically, there are first the lesions of mucopurulent bronchitis, without any peribronchial nodules in the strict sense of the term, but with an intense proliferation of the parietal epithelium. Secondly, the lesions of massive catarrhal alveolitis, with desquamation, proliferation and degeneration of the epithelial cells—epithelial pneumonia. Thirdly, alveolar serous hydrops, and fourthly, parietal interstitial serous infiltration. The contingent of both white and red corpuscles is relatively small when compared to the predominance, or at least the unusual abundance of, the epithelial element, with little or no fibrin.

In the infectious serosity, the only evidence of the general defense of the organism, in the absence of any considerable cell diapedesis, the inflammatory superactivity of the fixed cells—endothelialitis on the pleura, epithelialitis in the lungs—attests to the intensity of the local defense. Briefly, there is edema with alveolar and interstitial hydropsy and epithelial desquamation, but this edema is infectious, as is proven by the bacteriferous serosity and epithelial proliferation and degeneration.

These infectious edemas should be treated as if the lesion were a mechanical one, by milk diet, local blood-letting, digitalis and preferably theobromine. Medication likely to keep up or to increase the edema—the iodides, saline solutions, tuberculin, adrenalin—are to be rigorously avoided. But above all, in cases of pneumococcal infection care must be taken *not to treat the case as one of tuberculosis*. Should a pleural collection exist, thoracentesis is to be prudently done, as a pre-existing infectious edema might produce a mechanical edema *a vacuo*.

INTRABRONCHIAL INJECTIONS IN THE TREATMENT OF PULMONARY GANGRENE.

THE use of intrabronchial injections in cases of abscess and gangrene of the lung was introduced by Lajarige in 1893. The method seems not to have been adopted very widely. Some ten years ago, however, Guisez took it up and has developed a technique which he has applied in a large number of cases. The field of the injections in practice has been narrowed to abscess and gangrene of the lung in which conditions it is said to give results of value. Guisez has apparently used only disinfectant injections and has felt no necessity for injecting antisera. Besredka made the latter suggestion based on the results of animal experiment and Rathery and Bordet and Renon and Mignot have practised such intrabronchial injections of antisera for grippal and other bronchopneumonias. The author, however, is interested only in gangrene of the lung as a condition in which the best results are obtainable by disinfectants. The amount injected

into a bronchus is from 15 to 20 c.c. at a time and this dosage is necessary for good results. The screen shows the degree of penetration of the syringe nozzle and the latter is seen to pass the bifurcation and enter the desired bronchus. On one occasion the author saw on the screen the fluid itself enter the bronchioles. The larynx, including the initial portion of the trachea, must of course be cocaineized. Care should be taken that the cannula does not touch the tracheal mucosa during the injection which should be made drop by drop. Of a number of disinfectants tried the author prefers for the purpose gomenol given every two or three days. (*La Presse Médicale*, February 26, 1921, xix, 17.

The first patient mentioned with pulmonary gangrene recovered under the disinfectant treatment alone, and the author has relied on the latter exclusively throughout and has cured a number of cases. Ten histories appear in which the result so far as the gangrenous process was concerned was quite satisfactory. Only after a case of death from septicopyemia and another from meningococcus complications did he have to record failure. The diagnosis having been made by the x-ray to locate the gangrenous area the author begins his massive injections into the corresponding bronchus. The number of injections given varies considerably but in some obstinate cases it reaches twenty or more. The success of the treatment is shown by the gradual disappearance of fetor, the abatement of cough and expectoration, the general betterment and the retrogression of the disease focus, as shown by the x-ray and physical diagnosis. Temperature curves show either sudden or gradual improvement. When studied carefully several cases showed a tendency to exacerbation after the initial improvement, but followed by renewed benefit up to recovery. In the appended histories we find no allusion to other treatment, either local or general. The oil was used in 10 per cent. solution.

EDEMA DISEASE AND HYPOPANCREATISM.

DURING the course of the war but little authentic information was obtainable concerning the edema attributed to subalimentation. For one reason it appeared to develop chiefly in the Teutonic countries and the local accounts of the disease reached us only sparingly in abstracts from the journals of neutral countries. The first satisfactory description of it we find in an article by Weltmann of Professor Chvostek's clinic which appears in the *Wiener Archiv für innere Medizin* for December 15, 1920, ii, 1. The paper is largely a personal one including an account of three cases. The disease has vanished since the war, without leaving a trace. Studies of it must be limited to records made in the past, preferably since the war, or under the more favorable conditions of post-war times for study. One case was seen in 1919, another in 1920, and the third is without date. The first case is summed up as follows: an imbecile-degenerate woman of 40 had subsisted almost exclusively for

several years on a carbohydrate diet. She developed an attack of edema and diarrhea with intact heart and kidneys. The blood was hydremic and the transudates extremely poor in albumin. There was complete absence of HCl in the gastric juice. Sodium chloride caused diuresis but if combined with sodium carbonate the diuresis was inhibited while the edema was aggravated. Sodium carbonate alone in large doses increased the dropsy while HCl and pepsin started up diuresis. The diarrhea could not be arrested: on examination there were present in the stools fat, undigested meat, and much sodium chloride. The condition became progressive, cachexia developed, and death occurred after deep coma, preceded by an acute hemorrhagic diathesis and polyneuritis. Autopsy showed high grade atrophy of the pancreas.

The second case was very much like the first throughout and autopsy showed atrophy of the pancreas and likewise of the ovaries and suprarenal cortex. The Langerhans cells of the pancreas did not share in the atrophy. There is no mention in this case of a polyneuritis. The third case, also in a woman, considerably older than the preceding and apparently of ordinary mentality, presented the same symptoms as exhibited by the first two, including those of pancreatic insufficiency. But this case was complicated by a typhoid infection with bacteriemia and strongly positive Widal. The stools also contained the bacillus. The specific fever was distinctly abortive although a parotitis developed. Glycosuria, present in this woman, is not mentioned in the other cases. Hydrochloric pepsin, and pancreatin promptly checked the diarrhea for a time. Death in this case was accelerated by profuse intestinal hemorrhages. Autopsy showed healed typhoid lesions and atrophy of the pancreas. The woman had had edema of the face for at least 3 years before her death.

The author concludes that none of these women was physiologically normal to begin with and that the pancreas was involved in the constitutional inferiority. Then came the years of privation, and the pancreas as the organ of least resistance became unequal to its task of assimilation of the almost exclusively starchy regimen. A vicious circle was now set up with development of cachexia, and owing to atrophy of the pancreas recovery was from the first impossible.

CANCER IN CITY AND COUNTRY.

AFTER Jessen had compiled cancer statistics for the city of Basle it occurred to him to obtain the figures for the country section of the Canton for the sake of a comparison (*Schweizerische medizinische Wochenschrift*, April 7, 1921, ii, 14). The research was thorough and figures were compiled for each localization of the disease. Beginning with cancer of the tongue, the number of cases during 18 years for the rural districts was but 9 of which but one occurred in a woman, while for the same period in the city the figures were 37 with 7 of these in women. Reckoning the populations of the communities the frequency ratio was about $2\frac{1}{2}$ to 1 in

favor of the urban section of the Canton. Other statistics readily bear out the generalizations that cancer of the tongue is considerably more common in urban communities and that it is relatively rare in women. A conservative estimate is that cancer of the tongue is twice as common in cities. In cancer of the larynx there is little if any difference in urban and rural incidence, this localization likewise preferring the male sex. In cancer of the esophagus, which is also much more common in males, there is practically no difference in the incidence according to habitation. Of great interest are the figures for cancer of the stomach, and contrary to the general belief there is slightly more of this lesion in the rural than in the urban districts. But in the city the women victims outnumber the men, while in the country there are many more male victims. Cancer of the rectum is as common in one locality as the other and this is true of cancer of the breast, but cancer of the uterus is somewhat more common in the city. The above figures, which extend back less than 20 years, have no bearing on the problem of cancer increase, but elsewhere Jessen has shown that in Swiss cities cancer has increased notably during the past 50 years.

HYPNOTIC PUGILISM.

THE copy makers of sporting news for the daily press cannot be accused of overlooking data which make for sensational news and the same may be said truthfully of the cartoonists who illustrate sporting events. But to the best of our knowledge and belief there is one piece of news which they failed to take advantage of. An account was given in an issue of *la Psychologie appliquée* during 1920 (the *Gazette hebdomadaire des sciences médicales de Bordeaux*, April 24, 1921, xlii, 17, from which we quote, fails to give the number of the issue), of the award to the pugilist Carpentier of 10,000 francs for his services in elevating his particular branch of sport through his personal character and intelligence. The prize in question is known as the *grand prix Deutsch* and the award was made at one of the reunions of the *Académie des Sports*. In connection with this award the writer in the psychological journal prints the startling rumor, apparently in good faith, that Descamps, the trainer and manager of the boxer, hypnotizes the latter before sending him into the ring. After he has him in the state of hypnotic suggestibility he impresses him with statements that he is invincible, that he will feel no pain from the blows, that he will not tire, and so on. The sport writer often claims that one boxer has his antagonist under a sort of hypnotic spell by indirect waking suggestion variously conveyed, of which many examples are given; but that a boxer himself should be under volunteer hypnosis is seldom mentioned. This point may have been utilized in short story writing about boxing matches, but in the forthcoming event between the French boxer and Dempsey, no scribe has as yet made space out of the subject, or if he has done so, it has not received the degree of publicity that one would anticipate. Some years ago it was asserted that one of the leading actresses of the day obtained her talent, or at least the ability to exercise it, through hypnosis, and the story of Trilby is well known, but slugging under hypnosis is new.

News of the Week.

New Hospital at Spring Lake.—The Ann May Hospital at Spring Lake, N. J., was formally opened on National Hospital Day, May 12.

Medical Alumni Dine.—About fifty members of the Class of '96 of the New York University Medical School commemorated the twenty-fifth anniversary of their graduation at a dinner at the Hotel Pennsylvania on the evening of May 7. Dr. Van Beuren Thorne is president of the class.

The Dental Society of the State of New York held its annual meeting at the Hotel Commodore, New York City, May 11-13. This is the first time this organization has met in New York City.

Cholera and Typhus Threaten Moscow.—A despatch from Riga, Latvia, reports that cholera and typhus have broken out in Moscow. The Soviet Government is much alarmed over the situation and has ordered a general clean-up of the city from June 5 to 18.

Typhoid Fever a Vanishing Disease in Baltimore.—The figures of the Baltimore Health Department show that the death rate from typhoid fever, once so high in that city, has been cut to a fraction of its former size. In 1910, 235 deaths were charged to typhoid fever; in 1915 the number dropped to 128, and in 1920 there were only 35 deaths charged against typhoid fever. In 1920, 270 cases were reported, but it was shown that 96 were brought definitely from other places. The results achieved are attributed to carefully guarding the water and milk supplies of the city.

Improvements for Pennsylvania Hospital.—At the annual meeting of the board of managers of the Pennsylvania Hospital improvements, additions, and alterations to the extent of \$5,500,000 were recommended. These plans call for a new out-patient and emergency building, new heating plant, a nurses' home, a storeroom and the erection of a separate building for private patients, with a capacity of one hundred beds. These improvements will not alter or affect the old buildings in the hospital grounds. It is proposed to finance the project through an additional endowment fund of \$2,000,000.

Missouri Doctors Form Public Health League.—About five hundred doctors from St. Louis, Kansas City, St. Joseph, and other parts of the State, held a meeting in St. Louis, on April 26, to organize the Missouri Public Health League, an organization in the interest of health and public instruction. A resolution was adopted to proceed immediately to invoke a referendum on Senate Bill No. 433, passed at the last Legislature, which amends the law governing the granting of certificates to practise medicine in Missouri. A council was appointed which will endeavor within the next six weeks to arouse public interest against the bill. The bill on which the referendum is sought amends the law requiring that applicants for license to practise medicine shall be graduates of a "reputable" medical school so that it reads shall be graduates of "some medical college." The bill further amends the law so as to permit an aggrieved applicant to appeal from the decision of the State Board of Medical Examiners.

Tuskegee Medical Course.—The Tenth annual clinic of the Tuskegee Institute, Tuskegee, Ala.,

was held during the month of April, at which more than 1000 medical cases were treated, and 60 operations performed. Among those from a distance who took part in the clinics were Dr. E. H. Carey, Dallas, Tex.; Dr. Frank R. Ober, Boston, Mass.; Dr. J. Whittridge Williams, Baltimore; Dr. James S. Stone, Boston; Dr. Frederick R. Green, Chicago; Dr. M. L. Goodkind, Chicago; Dr. H. A. Royster, Raleigh; Dr. John E. Cannaday, Charleston, W. Va.; Dr. Fred H. Clark, Oklahoma City.

Ban Medical Student Bill.—The Commissioners of the District of Columbia have sent an objection to Senator L. H. Ball, chairman of the District Committee in the Senate, against a bill to amend the law governing the practice of medicine so as to permit students taking the examination to claim credit for study time spent in the office of a doctor. The commissioners object to the bill on the ground that it would lower the standard of medical education in the District of Columbia and that therefore it should not be enacted.

Campaign Against Rabies in New York City.—Following the death from rabies of a resident of Brooklyn who was bitten by a stray dog, the Health Department states that during the first three months of 1921, twenty animals examined at the laboratory of the Department of Health were found to be suffering from rabies. This is the largest number that has been reported for three months during a period of many years. The Health Department warns the owners of dogs that they will be required to observe strictly the muzzling ordinance.

Industrial Corporation Aids Public Health.—In cooperation with the New York City Department of Health's measures to prevent smallpox, the Western Union Telegraph Company, in the future, will require all applicants for employment to present certificates of recent vaccination.

Telephone System for Locating Physicians.—Des Moines, St. Louis, and St. Josephs have installed telephone exchanges for physicians, and Sioux City is to have a similar system by July 1. The service is exemplified as follows: When an emergency arises and a person wishes to locate his family physician who is a member of the exchange either at his office or residence, by referring to the telephone book he finds the line, "if no answer call No. ———," and the exchange immediately gets in touch with the physician wanted either by phone or messenger.

Charity Patient Disappears With Radium.—The treatment of a charity patient in an Oklahoma City hospital has resulted in the loss of radium valued at between \$3,000 and \$3,500 by a group of doctors in that city. The radium in two needles was placed in a cancerous growth. The patient disappeared with the radium on May 8, and police investigation has failed to reveal any trace of his whereabouts.

Drug Convictions Stand.—The conviction in the United States District Court of Dr. Daniel J. Hoyt and Dr. Leopold Harris, New York, charged with violation of the Harrison narcotic act, was recently confirmed in a decision by the United States Circuit Court of Appeals. Both physicians were convicted in May, 1920, of dealing in wholesale commercial prescription of drugs. Dr. Hoyt was sen-

tenced to serve four years and Dr. Harris two years in the Federal penitentiary in Atlanta.

Physicians Lease Office Building.—According to the real estate news, a group of physicians have leased the former home of Peter Doelger, Jr., at 266 West End Avenue, New York City, for a period of fifteen years at a total rental of \$200,000.

United Hospital Fund Distributed.—In connection with the celebration of National Hospital Day by appropriate exercises in the various hospitals of New York City, the United Hospital Fund announced the distribution of \$625,000 to fifty-six non-municipal hospitals, the amount going to each hospital being based on the extent of free work done by it irrespective of race or creed. Of the general hospitals, Mt. Sinai received the largest contribution, \$41,729, and St. Luke's came second, receiving \$35,974. Brooklyn hospitals received \$88,663.90. There were more than 10,000 contributors to the fund.

Madame Marie Curie, who arrived in this country on May 11, received the honorary degree of Doctor of Science at a special convocation of Smith College on May 13. President William Allan Neilson conferred the degree.

Dr. Charles E. de M. Sajous has been appointed professor of applied endocrinology in the Graduate School of Medicine of the University of Pennsylvania, and Dr. George B. Wood has been appointed professor of laryngology. Both men will assume the duties of their new positions next autumn.

Dr. E. M. Holder has been elected chief of the division of surgery of the Tennessee College of Medicine, to succeed Dr. McIver Woody, resigned.

Ex-Surgeon General William C. Braisted, U. S. N., has been chosen president of the College of Pharmacy of Philadelphia.

Dr. Alden Coffey has been appointed a member of the Board of Health of Fort Worth, Texas.

Reunions of Medical Men in Boston.—THE ALUMNI ASSOCIATION OF JEFFERSON MEDICAL COLLEGE, Philadelphia, will hold a reunion during the week of the annual meeting of the American Medical Association in Boston. All graduates are invited to register at the Jefferson table in the Convention Hall and give their Boston address. Dr. Wallace P. MacCallum, 214 Huntington Ave., Boston, will act as secretary.

THE PHI ALPHA SIGMA MEDICAL FRATERNITY will hold a reunion for members during convention week. Dr. E. J. G. Beardsley will act as secretary at the Hotel Brewster.

ALL OFFICERS AND MEMBERS OF BASE HOSPITAL 89 are invited to sit down to mess during the Boston meeting. Dr. Walter S. Lucas, secretary, will be at the Hotel Brewster during the convention.

New York State Narcotic Law Abolished.—Governor Miller has signed the first Lord bill which repeals the narcotic drug law, so that now the Harrison law alone is in force in this State. The Fearon bill was vetoed.

Alliance of Columbia University and Presbyterian Hospital.—According to an announcement made by the authorities of these institutions, plans for the alliance of the College of Physicians and Surgeons of Columbia University and the Presbyterian Hospital, which for various reasons have been held in abeyance, are soon to become

an actuality. Gifts totaling \$11,000,000 already have been received for a site, buildings and endowment, and it is estimated that from \$3,000,000 to \$4,000,000 additional will be required. Under the terms of the agreement for permanent alliance, Columbia University and the Presbyterian Hospital each continues its independent existence and control while providing a common administrative board for the oversight of the joint enterprise. New buildings are to be provided for both the medical school and the hospital between Broadway and Fort Washington Avenue, and 165th and 168th streets. This land has been given by an anonymous donor and is valued at \$1,000,000. The new administrative board is composed of John G. Milburn, Walter B. James, and William Barclay Parsons, representing the University, and Edward S. Harkness, Henry W. deForest, and William Sloane, representing the hospital. It is stated that Dr. William Walker Palmer, an associate professor in the College of Physicians and Surgeons until he joined the staff of Johns Hopkins University two years ago, is to be the new professor of medicine in the College of Physicians and Surgeons and the chief of the medical service in the Presbyterian Hospital.

Bellevue Without a Death.—For the first time in five years a period of twenty-four hours, on May 14, passed without the registration of a single death in Bellevue Hospital. A total of 1,400 patients were receiving treatment during this period. The record is considered unusual because of the seriousness of most of the cases brought to Bellevue.

Obituary Notes.—Dr. TITUS MUNSON COAN died at his home in New York City on May 8, at the age of eighty-three years. He was a graduate of the College of Physicians and Surgeons, New York, in 1861, and a Civil War veteran. He was one of the collaborators of the Standard Dictionary and a writer on medical and other subjects.

Dr. J. H. CONNOR, formerly of Superior, Minn., a graduate of Rush Medical College in 1883, died of apoplexy in Eau Claire, Wis., on April 23, at the age of sixty-two years.

Dr. MACCLAREY WEEKS of Galesburg, Ill., a graduate of the Northwestern University Medical School, Chicago, 1902 at one time president of the Knox County Medical Society, died suddenly on April 19, at the age of forty-two years.

Dr. RALPH W. MONTELIUS, Lieutenant-Colonel N. G. P., retired, died of pleuro-pneumonia at Mount Carmel, Pa., April 19. He was graduated from Jefferson Medical College in 1876.

Dr. F. D. WRIGHT, a graduate of Rush Medical College in 1882, died at the Christian Hospital, St. Louis, of a complication of diseases on April 18, at the age of sixty-five years.

Dr. ARCHIBALD L. MUIRHEAD, professor of pharmacology and former dean of the college of medicine of Creighton University, Omaha, died on April 24, at the age of fifty-five years. He was graduated from the University of Michigan Department of Medicine in 1893, and was for eight years editor of the *Medical Review*. He was formerly a member of the Nebraska State Board of Health.

Dr. AUGUSTUS BRYANT SHOLARS of Little Rock,

Ark., a graduate of the University of Louisiana Medical Department in 1861, died at his home on April 26, at the age of eighty-four years. He served as a surgeon in the Confederate Army during the Civil War.

Dr. GEORGE L. SMITH of Jefferson, Wis., a graduate of Rush Medical College in 1879, died at his home, on April 16, at the age of sixty-six years.

Dr. WILLIS E. STERRS of Albany, Ala., was accidentally drowned on April 26. He was a graduate of the University of Michigan Medical Department in 1888, and the founder of the Cottage Home Infirmary, the first hospital for Negroes in that section of the country.

Dr. ROBERT C. YENNEY of Portland, Ore., died suddenly of heart disease on April 24, at the age of fifty-two years. He was a graduate of the University of Pennsylvania Medical Department in 1892. He was a Lieutenant-Colonel in charge of a hospital unit on the Western Front during the war and also a Spanish War veteran. From 1904 to 1909 he was secretary of the Oregon State Board of Health.

Dr. M. L. WOLFORD of Harrisburg, Pa., a graduate of Jefferson Medical College in 1880, died of apoplexy on April 28, at the age of sixty-eight years.

Dr. OLIVER T. EVERHART, a graduate of the University of Maryland School of Medicine, died at his home in Hanover, Pa., on April 28, at the age of eighty-nine years.

Dr. BENJAMIN R. PELTZ of Roxborough, Pa., a graduate of the University of Pennsylvania Department of Medicine in 1867, died in a local hospital on April 28, at the age of seventy-eight years.

Dr. PAUL J. ANDERSON of Oakland, Cal., died in Honolulu of complications following pneumonia, on April 20, at the age of thirty-five years. He was a graduate of Cooper Medical College in 1910, a member of the American Neurological Association and the American Medical Association. He was for many years connected with the Alameda County Hospital and the Berkeley Dispensary.

Correspondence.

THE PRESENT STATUS OF THE SURGICAL TREATMENT OF CANCER.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—My attention has been called to an article by Dr. L. Duncan Bulkley in the MEDICAL RECORD, which has been copied verbatim in the *New York World*. As it is calculated to give the public an erroneous idea of the present status of the surgical treatment of cancer, I take the liberty of calling attention to the fact that arguments based on imperfect statistics are no longer tenable. The time has passed when we can say, with the French cynic: *Donnez moi des chiffres, je vous prouverai tout*. The American Society for the Control of Cancer is generally regarded as engaged in an altruistic movement, the professional standing of the directors (the list of whom I inclose) being such that they cannot be regarded as "overzealous surgeons throughout the country," or men who "acknowledge that 90 per cent. of those once attacked by cancer die therefrom." We are not bidding for operative work, but are

aiming at prevention and early diagnosis, rather than capital surgery in advanced cases.

Our statistician, Mr. Frederick L. Hoffman, than whom there is no more thorough and conscientious specialist in this line, has recently proved that since the year 1915 the mortality from cancer throughout the United States has *not* increased, but has remained steadily at 80 per 100,000.

We do not care to discuss the value of radium in the treatment of cancer, as it is evident that Dr. Bulkeley has not given sufficient attention to this subject to speak *ex cathedra*, neither do we refer to the work of the pathologists, who are able to speak for themselves. The claim that early cancerous lesions (and even metastases!) can be "made to disappear . . ." and that "the patient remains well indefinitely," with "minute and proper dietetic, hygienic and medical treatment" we do not pretend to discuss, having had no experience along this line.

HENRY C. COE, M.D.

NEW YORK.

ONE MEDICAL SCHOOL AND ONE FACULTY FOR ONE GREAT UNIVERSITY OF GREATER NEW YORK.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—Every American physician, and for that matter, every American citizen, will rejoice on learning of the contemplated establishment of a great medical center in the City of New York. It is announced that the authorities of Columbia University and the Presbyterian Hospital, who have \$15,000,000 at their disposal, have allied themselves in a stupendous program to create the world's greatest institution of medical learning.

Before the world war American physicians looked upon Berlin, Paris and Vienna as the great centers for medical learning. One might wonder why London never had the same repute and was never considered so great a medical center as the other three capitals. Conditions in London are somewhat analogous to those in the great cities of our own country. There as here exist several schools connected with hospitals which train physicians independently and give diplomas. The reason why Paris, Vienna, and Berlin were visited for post-graduate instruction by American physicians more frequently than London, in spite of the fact that in the latter city they had no difficulty with a foreign tongue, lies in the superiority of the facilities which a great single school can offer to the student. When there are several medical schools in one city, rivalry is inevitable. The more powerful and richer institutions will draw the better and more distinguished teachers from the less rich and less powerful and thus weaken the latter's prestige. The larger school can demand a higher tuition fee and a poor student, no matter how talented, cannot enter the great school which he knows would give him a greater prestige on graduation.

Never before has there been such an opportunity to unite the three medical schools of Manhattan and even the Long Island College of the Borough of Brooklyn into one great medical department of a newly created single university such as would result from the combination of Columbia, New York

University, and Cornell, after the pattern of the University of Paris. This unification could begin with the consolidation of the 3 or 4 medical schools. Paris, with its 4,000 to 5,000 medical students, offers the greatest possible clinical facilities in its many hospitals and laboratories for graduate and post-graduate instruction. Students are assigned to the hospitals as pupils, externs and interns for from 3 to 4 years. The first two years are mainly devoted to dissection, laboratory and practical work and to theoretical lectures. The remaining years are given to clinical instruction at the bedside and practical surgical training on the cadaver.

It was my privilege to have taken my degree the first time after only 3 years' attendance in one of our best American colleges, and the second time in Paris after nearly 5 years of hard work. On the strength of this experience of 8 years in medical schools as a regular student and some time spent in post-graduate work in Berlin and Vienna, and lastly as a teacher in an American post-graduate institution where physicians from all kinds of schools came to learn, I may be permitted to give my opinion as to how the contemplated venture may in reality make New York one of the greatest medical centers in the world.

Let the above mentioned four colleges unite as one great medical school with one faculty, one dean and four associate clinical deans to direct the clinical instruction. Thus, as in Paris, there would be several centers where anatomy could be taught practically. Let each large hospital have its own clinical laboratory, but all other instruction should be carried on at the Washington Heights Medical Department. Let there be a reasonable fee of tuition which will enable the student in moderate circumstances to enter. Every graduate should have at least one year internship in a hospital recognized by the faculty as in good standing. Examination for hospital internship should be done away with, the final examination and the record of the student's work should give him priority in the choice of the hospital in which he desires to serve as intern. There are enough hospitals in or near New York to give every student graduating from this school an opportunity to serve one or even two years as intern. While post-graduate students should be welcomed to the school for research work and clinical instruction, the greatest attention should be paid to the regular students of the University and they should be given preference in instruction and opportunity for clinical work. In the fifth year of his medical training the student should be left a free choice concerning what general or special clinics he would wish to attend, or what particular lectures by certain teachers he would wish to hear. This should in no way interfere with his final examination for his degree.

From what I have seen of medical colleges, students and teachers in this and many other parts of the world, it is my firm conviction that if the American medical schools in our various cities would each unite into one great faculty working under a single great university, they would, with the superior practical and ingenious methods of work of the American medical and surgical teachers, accomplish greater results than any European school in existence. So let us do away with the multiple medical local colleges and unite into one

great medical faculty and under one single University of the City of Greater New York.

Perhaps the various schools of law, pedagogy, sciences, etc., may later on be willing to follow our example, but in the meantime let us show to the world that American medical science is truly altruistic and in earnest and that New York physicians in particular, in their desire to create the greatest medical center in our metropolis, are willing to give up their individual preferences or ambitions and uniting in the work to make the teaching of the healing profession the best and noblest work there is. Thus may we alleviate human suffering, prevent and cure disease and work for the glory and physical and moral good of the nation and of mankind at large.

S. ADOLPHUS KNOPF, M.D.

NEW YORK, May 16, 1921.

OUR LONDON LETTER.

(From Our Own Correspondent)

LONDON, April 26, 1921.

Birth Rate of England and Wales.—The provisional figures of births registered in England and Wales during the first quarter of 1921 show a decline of over 61,000 from the record of the corresponding period of last year. Compared with the first quarter of 1914, however, the drop in numbers is under 8,000. Excluding the war years, the births are the fewest recorded in the first quarter of any year since 1872, and the provisional rate per 1,000 living is, with the exception of the war years, 1916-19, the lowest ever recorded for any first quarter. The deaths also show a decline and are, indeed, the smallest in number registered in the first quarter of any year since 1868, and the provisional rate is the lowest ever recorded for any first quarter.

Report of the Medical Officer of the County of Norfolk.—The reports of the medical officers for the counties of England and Wales have been issued recently and provide valuable information. Among these instructive documents, some of which have been referred to in previous letters, that of Dr. J. T. C. Nash, the medical officer of the County of Norfolk, is especially interesting. It is an exhaustive report, crammed with statistics and minute details. It also contains summaries of the reports for the years 1915 to 1918, very useful for the purpose of comparison. Dr. Nash points out that new and important statutory duties of a medical nature have devolved upon county councils in promoting the health of the people, including maternity and child welfare, the treatment of venereal disease, the administration of the milk order, etc. Prior to the commencement of the war, practically the only medical duties undertaken were in connection with mental diseases and the medical inspection of school children. It was not until 1919 that the Norfolk County Council seriously considered a tuberculosis scheme, so that this huge undertaking had to be dovetailed in with other new schemes and has involved considerable congestion of work with which the Public Health Committee has had to deal. It must be borne in mind that a county annual report not only has to deal with the health activities in which the county council is itself engaged, but with the sanitary circumstances of all the constituent sanitary districts in the administrative

area. It is not only for the information of the county council but for the Ministry of Health and others who have not the same intimate knowledge of the area. Moreover, it is expected to contain matter which will be useful to district medical officers of health, and be a means for conveying information on health questions to the community at large. In the report for the year 1919-20, Dr. Nash gives the birth rate as 17.3 of the population and the infantile death rate as 79.1 per 1,000 births. The death rate at all ages was 14.3, that for England and Wales being 13.7. He finds that the death rates of pregnant and parturient women are somewhat in excess in Norfolk as compared with England and Wales, except in the years 1916 and 1917, when they were lower. The excess he attributes in part (1) to the lack of a sufficient number of qualified midwives; (2) to the lack of special hospital provision for difficult cases in scattered and sparsely populated villages; (3) to the inadequacy of some cottages for even a normal confinement; (4) to deficient nutrition of pregnant women. He proceeds as follows: "The indication is for the county council to meet factors 1, 2, and 3 by making arrangements with available hospitals or hostels for the reception of cases for which adequate provision at home is impossible, and to circularize midwives and practitioners of such provision, and for which grant is available. Factor 4 is largely met now by the administration of the milk order of 1919. The fact that maternal mortality was lower in 1916 and 1917, when income was better and rationing was in force, enabling all to get a share, is suggestive that nutrition is an important factor." He considers infantile mortality to be too high for a rural area, and attributes it to a want of proper nutrition for the mother and the absence of efficient dentistry, both of which conditions adversely affect the children. He urges the need for supervision of midwives, advice to expectant mothers, assistance at the time of confinement, and arrangements for dealing with postnatal matters. Dr. Nash speaks highly in favor of infant welfare centers, a number of which are successfully working in Norfolk. Referring to infectious diseases in Norfolk, he states that no person who has had enteric fever is fit to handle milk, which is a vehicle peculiarly adapted for carrying infection; indeed, he thinks it would be well if persons who have had enteric fever were debarred from any occupation in the preparation or distribution of any kind of food. He notes with satisfaction that there has been a marked and continued reduction in the incidence of enteric fever in England, and attributes this largely to the persistent warfare on boiled cockles from polluted layings, a means of precaution he initiated in the opening years of the century. He points out that the partial boiling of cockles, formerly so prevalent, does not destroy the poison germs; they must be thoroughly boiled. Dr. Nash devotes a considerable part of the report to tuberculosis, and points out that the year 1918 showed a marked increase in the number of deaths from tuberculosis, an increase due, he suggests, to the short rations of food, the strain of the culminating year of the war, and the terrible pandemic of influenza which swept the world in that year. He does not believe that there were more cases of tuberculosis in that year, but that

the constitutional factors then existing lessened the resistance of the tissues of persons affected with the disease. Hitherto, in his opinion, too much attention has been given to tuberculosis as a disease calling for specialized treatment and too little to its public health aspect, requiring the simultaneous adoption of preventive as well as remedial measures. Perhaps the main points in the report referred to above are the remarks on maternity and child welfare and infantile mortality. Dr. Nash believes that maternity and child welfare effort should, in the course of the next few years, reduce the average mortality of the twenty rural districts of Norfolk from 81.6 to 75; but the result can only be brought about if such effort is concentrated and adequate, and is specially directed to the adequate nutrition of expectant and nursing mothers and the encouragement of the breast-feeding of infants for at least seven to ten months after birth. As in Norfolk so in England and Wales as a whole, the care of the expectant mother and the management, medical, surgical, nursing and otherwise, of the parturient woman is, generally speaking, not in conformity with a high standard. It is allowed by the leading obstetricians of the country that the training of the medical student and nurse in this most important branch of surgery is inadequate. In country districts there is a lamentable lack of maternity homes, and the conditions in many, perhaps most, of the cottages are entirely unsuitable for the conduct of such a surgical procedure. As for the infantile mortality in Norfolk, Dr. Nash puts it down to prematurity and immaturity and holds that the diet of the mother plays a great part in producing these conditions. He points out that a diet of refined denatured foods will certainly lack necessary elements and will give rise to malnutrition and deficiency diseases. Hence the necessity for advocating the use of whole grains, containing all their natural salts and vitamins; for the daily consumption of fruits, vegetables and greens, remembering not to discard the water in which the latter are cooked, but to utilize them again in the forms of soups and sauces; for the use of natural sugars in preference to refined sugars. The report, indeed, like all the reports of the medical officers of health, is full of practical suggestions, and it would be in the interests of the health of the community if certain parts were extracted and reprinted for widespread distribution.

Post-Graduate Medical Education.—The advantages, or rather, the necessity, in these days of a well organized postgraduate medical education has been so often pointed out and are so obvious that further elaboration of the subject would seem to be superfluous. In America the importance of having such a system is well understood, but although a good deal has been done and more conceived and planned in this country, schemes in this direction appear to lag somewhat strangely. To the *Observer* of April 24 last, Mr. Percy Dunn, a well known London surgeon, contributed so excellent an article on the question that it will not be out of place to quote it at length: "The time is not far distant when postgraduate medical teaching will come to assume as much importance as the education provided for the medical student. Medical knowledge new today is often old tomorrow. It is only those in contact

with the centers of its advancement who can keep pace with its progress. An up-to-date, newly-qualified young house physician or house surgeon, appointed, let me say, to a country hospital or infirmary, is not infrequently called upon to "advise" his chief as to the latest method of treatment of cases. In former days this kind of thing was a common rule. The "chief" was usually a general practitioner in the town, who had for long lost contact with the advancement in his profession. It was only by continuous study of text books and regular perusal of the medical journals that he could keep himself up to date. But such a task was beyond him; he had no time to devote to it. Moreover, the value of text book reading is limited; it fails in supplying the practical factor which appeals to the eye and trains the hand. The times, however, have changed largely in comparison with those of the past. The practitioner of today is far in advance in professional knowledge of his predecessor. That knowledge has been gained under the modern system of medical education, more surely based upon a scientific foundation. But so it is that the more sure the foundation the greater becomes the opportunity for improving and elaborating the superstructure. Thus it has come to pass that medical knowledge is always advancing. One day it may be regarded as up to date, but the next day it is superseded by a new scientific development. Herein is revealed the extremely important utilitarian aspect of the value of postgraduate teaching. To place the advantages of postgraduate teaching upon its highest pedestal, the community, that is the nation, gains by the dissemination of up-to-date medical knowledge among practitioners in whose hands the care of the public health chiefly rests. But in order to carry through a scheme for the purpose of achieving this truly national object, the aid of a patriotic philanthropist is needed, and here it may be said that of the many great projects which have evolved themselves out of the brain of that incomparable organizer, Sir John MacAlister, the postgraduate scheme is his newest creation and one of the most important. His life has practically been spent in advancing the facilities for the progress of medical science. It is impossible to conceive of the greatness of the asset to British medical science which the creation of the Royal Society of Medicine represents. Never restful where progress is possible, about two years ago he founded the Fellowship of Medicine Post-Graduate Association. Struggling along successfully as it has done during the past eighteen months, attracting medical men from all parts of the world, the time has now come when in order to accomplish the full fruition of its objects financial aid is necessary. For the sum of £30,000 a benefactor could claim the honor of providing an "Imperial Post-Graduate Medical College in the Empire's centre, securing for British medical science the facility for world-wide dissemination. Capital alone is required for this Imperial object."

The above account describes the need for efficient postgraduate teaching in Great Britain, and the claims of London as a world postgraduate medical center clearly and well. It also gives honor where honor is due in describing Sir John MacAlister in whose brain was first conceived the

idea of making of London the medical center of Europe if not of the world, as an incomparable organizer. It may be added that of all the schemes in which Sir John MacAlister has played a leading part in initiating and developing, none has been nearer his heart than the present scheme. He is particularly desirous of attracting American medical men to London for postgraduate medical training, and with this end in view is sparing no effort to make their stay profitable from the medical and scientific standpoint and comfortable and pleasant from the social aspect. The lack of funds is the main impediment to its consummation, it is to be hoped however, that this will be removed soon and that as Mr. Percy Dunn anticipates an Imperial Post-Graduate Medical College will be founded in the largest English speaking city of the world.

Sir Squire Sprigge, editor of the *Lancet*, has been elected a Fellow of the Royal College of Surgeons.

1. Vitamins in milk. M. J. Rosenau.
2. A Review of Three Hundred Cases of Blood Chemistry.—Edward B. Bigelow, from this review, concludes that, in general, these examinations, whether they prove to be normal or abnormal, are functional tests of value in the fuller consideration of cases. Prognosis is extremely poor when there is a high retention of creatinine, and rather poor when there is a high urea retention. The determination of the alkali reserve is valuable in diabetes mellitus and to a lesser degree in nephritis. Repeated blood sugar determinations are invaluable as guides in the treatment of diabetes mellitus.

1. The Role of the Prostate and the Seminal Vesicles in Arthritis.—Oswald Swinney Lowsley, on a study of one hundred cases of gonococcus infection of the joints, occurring in Bellevue Hospital in the past two years, additional cases which have been treated by operation and otherwise during the past six months, and some cases which have been treated by palliative means. The investigation was conducted largely in the urological department. The majority of the patients, sixty-seven in number, were treated in the urological wards. Twenty-five were treated in the medical wards, and two in the gynecological department. Previous similar attacks had occurred in 15 per cent. of the cases, while 66 per cent. of the patients

complained of a previous gonorrhea. Twenty-nine per cent. denied previous attacks of either arthritis or gonorrhea. The knee was involved more frequently than any other joint. The results of treatment were not particularly brilliant in any of the series. Better results were obtained by operation and by cast methods than by any other, the period of residence in the hospital being two-thirds as long in the latter as in the former. The use of internal medication was productive of less improvement than any of the other methods tried. Local applications to affected joints proved beneficial in three-fifths of the cases tried. Gonococcus vaccine was beneficial in seven cases of eleven injected, and typhoid vaccine used in sixteen cases was at least temporarily beneficial in ten. Palliative treatment of the prostate and seminal vesicles resulted in two complete cures, five cases in which distinct improvement was noted, and two in which there was no improvement. Casts and splints were used in twenty-three cases. Improvement followed in less than 50 per cent. of the cases, but the series of carefully treated cases in which heavy casts were applied and the joints baked afterward were signally successful, all showing marked improvement. Operations upon the seminal vesicles showed improvement in nine out of ten cases. The writer concludes that no case of arthritis in the male adult is properly investigated unless a rectal examination is made. Prostatic fluid should be examined in the fresh state under the high power lens of the microscope to determine the presence of pus or pathological elements. The process of staining masks the true conditions in some instances. In chronic prostatitis the gonococcus is rarely met with.

1. Restoration of the Normal Cardiac Mechanism in Auricular Fibrillation by Quinidin: Preliminary Report. Robert L. Levy.
2. New Principles in Plastic Operations of the Eyelids and Face. Joseph Imre, Jr.
3. Increased Amount of Uric Acid in the Blood in the Toxemias of Pregnancy. J. Lisle Williams.
4. Hyperglycorachia in Epidemic Encephalitis. Harold E. Foster.
5. Infestation with Filaria Loa: Report of a Case of Filaria Beneath the Conjunctiva and Microfilariae in the Peripheral Blood Stream. Howell L. Beale.
6. Prevention of Acute Arspheamin Reaction by Antianaphylaxis and Atropin. George J. Busman.
7. Laryngeal Diphtheria: Review of Five Hundred and Fifteen Cases in Which Intubation Was Performed. Archibald L. Hoyne.
3. Increased Amount of Uric Acid in the Blood in the Toxemias of Pregnancy.—J. Lisle Williams, after a large amount of uric acid had been found in the blood of a patient with eclampsia, made more detailed chemical studies of the blood of patients with the so-called toxemias of pregnancy. The results of the chemical examinations of the blood of twenty-five patients with eclampsia, preeclamptic toxemia, or pernicious vomiting of pregnancy demonstrate that the uric acid regularly exceeds the normal in the blood of these patients, whereas the other nonprotein nitrogen constituents usually are not increased. Study of the blood of these twenty-five patients, and of six pregnant women with none of the mentioned, studied for purposes of comparison, the following conclusions are drawn: 1. In the blood of patients with eclampsia, hyperemesis gravidarum, and with the symptoms of preeclamptic toxemia, together with arterial hypertension, the uric acid is markedly increased. 2. Delivery and recovery from the symptoms are associated with a gradual return of the uric acid in the blood to its normal amount. 3. Arterial hypertension in pregnancy unassociated with toxic symptoms is not unaccompanied by uric acid retention. 4. The toxic vomiting of pregnancy is associated with a marked increase of the uric acid in the blood, whereas the nervous or physiologic vomiting is not. It seems possible, therefore, to differentiate these conditions by quantitative estimations of the uric acid of the blood.
4. Hyperglycorachia in Epidemic Encephalitis.—Harold E. Foster states that hyperglycorachia is usually present in epidemic encephalitis. This small series (eleven cases) would indicate that there is a definite relation to the intensity of the clinical picture. There seems to be no definite relation to the duration

of the disease. There is no evidence of a corresponding glycemia or glycosuria. It appears to be the only test which is characteristic of this condition, and in the absence of a distinctive pleocytosis, total protein content or colloidal gold reaction, it is of value as an additional diagnostic aid and possibly is of prognostic importance.

6. **Prevention of Acute Arspenamin Reaction by Antianaphylaxis and Atropin.**—George J. Busman made an examination of the records of the Section on Dermatology and Syphilology of the Mayo Foundation with reference to arspenamin reactions, finding thirty-six cases in which the recurrence of arspenamin reactions, of both the nitritoid and gastrointestinal types, was so persistent that it was impossible to ascribe it to incidental or temporary fluctuations in the technique. His findings are summarized as follows: 1. The exact nature of nitritoid and gastrointestinal reactions to arspenamin is undetermined. It seems not improbable that a variety of causes may act to produce a single syndrome of which the acute reaction on the table, and in certain cases, the late gastrointestinal reaction, may be phases of the same phenomena. 2. In the group of cases reported, repeated nitritoid crises, associated with repeated gastrointestinal reaction, persisted regardless of any controllable factor in the technique. 3. Repeated uncontrollable acute reactions are interpreted as personal idiosyncrasies of the patients to the drug. 4. The observation of Stokes on the value of atropin and of induced antianaphylaxis (Besredka technique) in the control of a persistent tendency to acute nitritoid crises is confirmed. 5. It has been further found that a tendency to repeated late gastrointestinal reaction can also be controlled in a large number of cases by either method alone, or by a combination of the two methods. 6. Atropin is sometimes effective in doses less than 1/50 grain. It may fail entirely to effect reaction even in doses of 1/50 grain. 7. A combination of the use of atropin and the induction of antianaphylaxis by dividing the dose of arspenamin is more effective than the employment of either method alone. 8. A combination of the two methods may make possible the continuance of arspenamin treatment in patients in whom repeated severe reaction would otherwise force its abandonment.

2. **General Indications for Operative Exploration in Nerve Injuries.**—Harry Platt emphasizes, in the beginning of this discussion, that it is impossible to enunciate any hard-and-fast rules in connection with the indications for the operative exploration of an injured nerve trunk. An exploratory is either justified, or is inevitably needed, under the following conditions: 1. Where the syndrome of complete interruption has persisted unchanged after a period of observation during which repeated clinical examinations have been carried out. As a working plan, a period of observation lasting six months is reasonable, although it must be admitted it is essentially an arbitrary one. With regard to the stage of safety, after complete healing of the wound a period of four to six weeks should be taken as a minimum, but may be prolonged according to the influence of local conditions. 2. Where the syndrome of incomplete interruption has continued without change for six months and particularly when this is represented by the distal syndrome. 3. In the presence of the syndrome of irritation, either of a moderate degree showing no signs of subsidence, or in the severe type—causalgia—at the earliest possible moment. The preparations for the operation; the exploration technique proper; the general indications for the choice of

the particular type of operative repair, and an analysis of 510 operations performed in the writer's services from March, 1915, to December, 1920, are given in detail.

3. **Researches on the Biochemistry of Germs and Other Proteins, with Special Reference to the Problems of Immunity.**—David Thomson, in this first communication, deals with the splitting of germs and other proteins into their component parts. The biochemical researches involved were begun in 1917, at a time when the writer was engaged largely in growing the gonococcus and in making large quantities of gonococcal vaccine for the army. Having ascertained that the gonococcus substance (thrown out of solution by acidification) is antigenic, he commenced to test the therapeutic value of this precipitate by subcutaneous injections in gonorrheal subjects. It was found, after many injections, that the precipitate was some 50 times less toxic than the actual untreated gonococci themselves. Moreover, the larger doses of the nontoxic precipitate appeared to confer more immunity and gave better therapeutic results than the necessarily smaller doses of the untreated germs. Having ascertained that the gonococcus protein precipitate thrown down by acidification was comparatively nontoxic, it naturally occurred to him that the toxic properties of the germ would be found in the acid supernatant fluid, which was separated from the precipitate by centrifuging or by filtration. This belief proved to be correct; small doses of the supernatant fluid caused quite an intense local reaction when injected subcutaneously. The acid supernatant fluid was neutralized before injection, so that the local reaction produced was not due to the acidity of the fluid. This supernatant fluid has also a provocative effect in the disease, since it increased the symptoms and renders the urethral discharge more profuse. It was found to contain protein substances which can be precipitated by the addition of picric acid, ammonium sulphate, or absolute alcohol. These preliminary researches on the gonococcus led to a similar study of other pathogenic organisms and of proteins in general. First of all a series of parallel experiments was carried out on germ protein (gonococcus), animal protein (ox heart), and vegetable protein (pea flour). The gonococcus, minced ox heart, and pea flour were easily soluble in N/1 NaOH, but a certain proportion of undissolved substance remained which could be removed by filtration. From these tests it appears evident that the meat (ox heart), the gonococcus, and pea flour, are very similar in nature, and that all three substances consist largely of protein, which can be split up into metaprotein, primary proteose, and deutoproteose. The nontoxic gonococcus vaccine consisted of gonococcus metaprotein, and the toxic supernatant fluid contained primary and secondary gonococcus proteose. Experiments on gonorrheal subjects showed that the primary and secondary proteoses from the gonococcus were no more toxic than the comparatively nontoxic metaprotein itself. They produced no marked local or general reaction, such as fever and malaise. It was noted, however, that an injection of these proteoses caused quite a definite provocative reaction at the focus of the disease, and a subcutaneous injection of the proteoses has been found useful as a provocative test of cure in gonorrhea. In gonococcal iritis an injection of the proteose may cause an acute flare-up in the eye; it is therefore not recommended as a diagnostic test in this condition. A certain amount of immunity appears to be developed against the proteoses, since after repeated injections they lose their focal provocative reaction. Other phases of the subject discussed by the writer are: Alkali solubility of other germs and proteins; further biochemical components of germs and other proteins, viz., acid-soluble, alcohol-soluble, and chloroform-soluble fractions; quantitative biochemical analyses of the gonococcus and the tubercle bacillus; content of different germs and proteins; same types but varying proportions of component substances, and antigenic and comparatively nontoxic nature of the protein split products described.

4. The Surgical Treatment of Chronic Sciatica.—J. Mill Renton holds that it is only in chronic cases that have failed to recover under medical treatment that there is any question of surgical interference. Not all chronic cases are suitable for operation, and it is necessary to differentiate them carefully by the symptoms to which they give rise. He roughly classifies them into three groups: 1. Cases in which the patient is quite free from pain while at rest, but begins to have pain on exercise or on assuming some special position. 2. Cases in which there is a certain amount of pain while at rest, but where it becomes really intense on exercise or on the assumption of a particular position. 3. Cases in which the pain is of an indefinite character, present at rest off and on, and sometimes improving to a certain extent on exercise. The operation is extremely simple, consisting essentially in the freeing of the sciatic nerve from adhesions. This is done by exposing the nerve below the gluteus maximus by a four to five inch longitudinal incision, hooking it up, and then carefully removing all adhesions from the sacro-sciatic notch to about the middle of the thigh. The adhesions may be fine and readily separated by the finger, or they may consist of strong bands that have to be divided. All tags and loose ends of adhesions should be dissected away. The branches to the hamstrings which come off just below the lower border of the gluteus maximus should be preserved. The nerve is then dropped back into the wound and the skin sutured. No splint is applied, but the patient is kept in bed for ten days and then allowed up.

1. Indications for the Treatment of Acute Appendicitis, from the Standpoint of the Surgeon.—Moses Behrend holds that greater care should be taken by the general practitioner in referring his cases earlier to the surgeon. This will reduce the number of drainage cases, which later are nearly always followed by an incisional hernia. Some types of acute appendicitis ought to be operated on at once. Others are benefited by a rest of a few hours by instituting the Fowler-Murphy treatment. Children should be operated on at once on account of the peculiarity of the appendix to undergo rapid inflammatory changes. The ability to diagnose the position and degree of inflammation depends solely on one's experience. While the value of the leucocyte count is not underestimated, the diagnosis of acute appendicitis is determined by physical examination. A leucocytosis is simply confirmatory evidence. In all pus cases one must get in and out as quickly as possible. Deep anesthesia is important. The appendix is removed in every case. The Ochsner treatment is no doubt valuable in the hands of those who understand its application. The writer never uses the Ochsner treatment. A mortality of less than 1 per cent. compares favorably with the results of surgeons who advocate this treatment.

1. Some Observations on Sprue and Its Prevalence in the South.—Sidney K. Simon briefly traces the history of sprue, and classifies the symptoms in a well advanced case into four cardinal groups: 1. An intensely red, desquamated, raw-beef type of tongue, accompanied in most instances by a general ulcerative stomatitis. 2. A greatly inflated abdomen, doughy in consistency, with enlarged intestinal coils often visible through the thinly stretched abdominal wall. 3. A chronic fermentative type of diarrhea characterized by unusually copious, pale-yellow and foul-smelling stools. 4. A progressive deterioration of strength, accompanied in most instances with marked pallor. Ashford's conclusions regarding the etiology of the condition, which he attributes to "*Monilia psilosis*," have not been entirely confirmed, although from a clinical standpoint the evidence appears convincing. The morbid lesions are not unlike those found in other forms of blastomycotic infections. The chronic, irregular course of the disease is certainly quite characteristic of this type of infectious process. Various dietetic methods of treatment have been employed, but complete unity of opinion is lacking. The one fact particularly noted by the writer in contemplating the various diets is that fat is the one element of food not tolerated in sprue. In three cases followed by him it was found that fat in any form immediately gave rise to disturbances of the intestinal function, followed by an outbreak of toxic symptoms. A liberal mixed diet, including skim milk, buttermilk, fat-free meat, and vegetables and fruits of several varieties yields the most satisfactory results in the dietetic management of the disease. Based upon the theory that the disease is of blastomycotic origin, due to specific infection with *Monilia psilosis*, efforts have been made, particularly by Ashford and his followers in Porto Rico, to prepare a vaccine for use in the treatment of sprue. Sixty-two cases were treated by Michel with a vaccine prepared after the directions of these observers, and it is claimed that forty-nine were discharged cured, twelve were improved, and one died. The vaccine treatment, in conjunction with the usual dietetic regulations, seems to offer the best results.

11. Apoplexy of the Placenta.—M. Pierce Rucker calls attention to the many theories that have been advanced as to the causation of solid areas in the placenta, to which various terms have been applied, as placentalitis, scirrhus, atrophy, hepatization, apoplexy, phthisis, fatty and fibrofatty degeneration of the placenta. Their macroscopic appearance naturally suggests the name placental infarcts, as they look like the familiar embolic processes found in the spleen and other organs. Sometimes the infarction is not white but red, suggesting hemorrhage. In the past three years the writer encountered six cases in which there were large red infarcts. The cases are reported in brief detail. From the study of the cases and the observations of others he concludes that the term apoplexy of the placenta would seem appropriate, first, on account of the hemorrhage usually present in these infarcts; and, secondly, on account of the rather sudden appearance of the clinical signs. The association of large white and red infarcts in the same placenta, the presence of necrotic areas in the center of many of the infarcts, and finally the presence of clotted blood in many of these infarcts with signs of premature separation of the placenta suggests that this may be the sequence of events in certain cases of ablatio placenta. This condition presents a definite symptomatology that makes it possible to recognize it by carefully observing the patient in the latter part of her pregnancy.

Book Reviews.

THE TREATMENT OF WOUNDS OF LUNG AND PLEURA.

Based on a Study of the Mechanics and Physiology of the Thorax. Artificial Pneumothorax, Thoracentesis, Treatment of Empyema. By Professor EUGENIO MORELLI, Assistant in the Medical Clinic of the Royal University of Pavia, Maggiore Medico, Field Hospital No. 79. Translated from the Italian by LINCOLN DAVIS, Formerly Lieutenant-Colonel, M.C., U. S. Army; and FREDERICK C. IRVING, Formerly Major, M.C., U. S. Army. Boston: W. M. Leonard, 1920.

This is a most interesting volume detailing a method of treatment which seems to merit wide acceptance as soon as it becomes generally known. The translators were close observers of Morelli's work and results at Ospedaletto 79, which was attached to the 11th Corps of the Italian Army, directed by Morelli and devoted exclusively to wounds of the lung and pleura. They had the opportunity of studying some hundred of these cases treated by Morelli during the final actions on the Piave and its vicinity, and from interested sceptics they were soon converted to enthusiastic adherents.

Before reaching the text there is first a Letter from the Author to the Translators, in the course of which Morelli pays a tribute to the late Dr. John B. Murphy because, although he had independently conceived and applied therapeutic pneumothorax almost contemporaneously with Forlanini, Murphy gave the honor of priority to Forlanini. Next, there is a Translators' Note; then an Introduction, written on his deathbed by Forlanini; and finally a Preface by the author, in the course of which he says: "I gratefully acknowledge that all I have to say is the direct germination of what my 'Maestro' (Forlanini) has taught. I have applied his ideas on the treatment of phthisis, pleuritis, and empyema to war wounds of the lung and their complications, modifying and adapting the technique only to the special conditions."

After a short preliminary chapter on mortality statistics and pulmonary physiopathology, Morelli discusses the symptomatology and clinical pathology of wounds of the lung and pleura. His method of treatment consists essentially in creating or prolonging a closed pneumothorax, with removal of hemorrhagic or other fluid under appropriate conditions and with proper regulation of the pressure of the pneumothorax. All the details of time, circumstances, and manner of performing these maneuvers are discussed exhaustively.

With the apparatus described and illustrated, production of pneumothorax is easy and perfectly safe, the latter being attested by the fact of his having induced pneumothorax more than 1,000 times without fatality. His method of making a closed wound of the pleural cavity out of an open one is ingenious and seems effective. An interesting chapter on the clinical examination of patients with wounds of the thorax is followed by the detailed case reports of 65 patients treated by Morelli's methods and a long discussion of the features brought out by these cases.

The book is intensely interesting, the method of treatment seems logical, the results seem almost miraculous in many cases, and it is to be hoped that the book will have a wide circle of readers, particularly among the leaders of the profession, both medical and surgical; for we feel that the author has elaborated a technique which, if widely known, would result in the saving of a great many lives that will otherwise be lost through the employment of the more common methods. This applies not only to cases of wounds and injuries of the lungs and pleura, which are comparatively uncommon in civil practice, but also to cases of empyema, which we almost always have with us.

THE DISEASES OF THE NEWBORN. By Dr. AUGUST RITTER VON REUSS, Assistant at the University Children's Clinic and Director of the Department for the Newborn at the First University Women's Clinic in Vienna. With Ninety Illustrations. New York: William Wood & Co., 1921.

How long may a child be regarded as newborn? Considering the influence of several factors, the author of this book gives the first two or three weeks of life after birth as the limit of this period, granting, of course,

individual variations in the child. Then it is that the influence of that much-stressed period in the Freudian theory (intrauterine) has not yet passed off, while an endeavor is being made by the new organism to learn rapidly the strange environment. It is this time of growth, development, and accommodation to a very new world on the part of the infant which seems to be debatable ground for both the pediatric and obstetrician, so far as responsibility for its physical health is concerned. It is to clear the field of any haziness in this important period that this book has been written. It is a most interesting compilation on the subject, covering first, the physiology, feeding, nutrition, and all normal aspects of the new life, then going into the pathological side of each system of the body. The premature baby is included, but it is somewhat of a misfortune that no reference has been made to the later development or adult life of the premature child. The book emphasizes the point of defective vitality which is often the share of the premature, due to his prematurity. This big fact is so seldom taken into account in the history of such an individual's life as maturity is reached, and may form a large part of the background for much that is not understood either psychically or physiologically by many medical minds in the later treatment of such cases. Of course the author credits syphilis as being the cause of many such births, but he is generous, and allows the mother a little latitude for other reasons why she should have precipitated into a strange world offspring so handicapped from the very beginning.

Why should not the premature baby be of most valuable assistance to the psychoanalysts? Since he has not had the full time allowed for suppression into the unconscious of his many intrauterine impressions, he would seem to be an extraordinary morsel of study for these specialists as he steps along through life. One or two months taken from the lap of luxury might be a deterrent to any individual no matter how sturdily made he might be! Since the author apparently finished this compilation in 1912 and sent it forth in 1914, although this is its first appearance here, he has not much to say as to the effect of the reactions of internal gland secretions on the newborn, either normally or pathologically. The bibliography covers fifty-three pages and is most complete. The work is a mighty convenient means to keep at hand all types of knowledge on the newborn babe for either the pediatric, obstetrician, or general practitioner, if there are any such left.

TROPICAL OPHTHALMOLOGY. By ROBERT HENRY ELLIOT, M.D., B.S. (Lond.), Sc.D. (Edin.), F.R.C.S. (Eng.). Late Superintendent of the Government Ophthalmic Hospital, Madras, and Professor of Ophthalmology, Medical College, Madras, etc., etc. New York: The Oxford University Press, American Branch, 1920.

This volume comprises ten sections of which the first is a general introduction, the second, devoted to the action of tropical glare as a factor in eye disease, the third, to the part played by winds and dusts, and the fourth, to direct injury by insects, tics, etc. The fifth section is devoted to parasitic affections originating within as well as locally. The sixth and seventh sections deal with cataract operations including the native procedure of couching. Section VIII is devoted to diseases of the lids, conjunctiva and cornea and lacrymal apparatus. Section IX comprises miscellaneous affections, errors of refraction, glaucoma and neoplasms. In the tenth section we find the local eye manifestations of constitutional diseases. This volume, which contains 511 pages, 117 text illustrations and eight colored plates, should be read by every practitioner. It sheds side lights not only on domestic ophthalmology, but all aspects of clinical medicine.

OTO-RHINO-LARYNGOLOGY for the Student and Practitioner. By DR. GEORGES LAURENS. Authorized English Translation of the Second Revised French Edition by H. CLAYTON FOX, F.R.C.S. (Irel.) With a Foreword Contributed by J. DUNDAS GRANT, M.A., M.D., F.R.C.S. With 592 Illustrations. New York: William Wood and Company, 1919.

THE "meticulous minuteness" with which the details are given in this volume of 324 pages of text, the comprehensive scope of the subject matter, the profuse illustration, and the full index, render this a valuable addition to the reference library of the student, the general practitioner, and the specialist.

Society Reports.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

One Hundred and Fifteenth Annual Meeting, Held in Brooklyn, May 3, 4, and 5, 1921.

SECTION ON SURGERY.

(Continued from page 855)

Wednesday, May 4—Second Day.

The Interpretation of the History in Surgical Affections of the Right Upper Quadrant.—Dr. CHARLES G. HEYD, New York City, made this presentation. His paper was a plea for the art, rather than the science, of medicine, as represented by the correlation of the history with the symptomatology. He said that of 100 people complaining of gastric distress, 20 would have symptoms due to organic disease; 40 would have disease remote from the stomach; 40 would have some pathological process outside of the abdomen. The differential diagnosis must be between carcinoma, appendicitis, pancreatitis, lesions of the kidney, of the gall-bladder, and of the colon. *Acute appendicitis* would give a history of pain, colic, fever, leucocytosis, nausea, vomiting, in the first twenty-four hours, and, secondarily, gangrene and perforation. On admission there was usually muscle spasm and abdominal rigidity. Chronic appendicitis had a different picture, difficult to diagnose, which must be differentiated from ulcer of the stomach, and from gall-bladder disease. Symptoms were variable; there was low epigastric pain, indigestion, not always attributable to the same type of food, sometimes there was even hematemesis. *Gall-bladder Disease:* The gall-bladder, pancreas, liver, and stomach should be considered one physiological system; infection being the etiological factor of the lesions. In 75 per cent. of gall-bladder cases there were stones; in 25 per cent. infective processes. Four clinical types existed: (1) Disease confined to the gall-bladder; (2) attacks of biliary colic; (3) calculous obstruction of the common duct; (4) associated pancreatic disease. The clinical picture of cholecystitis was due to the motor-secretory disturbance, characterized by vague irregular dyspepsia, fullness, weight, distress, gas eructation after fatty foods; vomiting relieved the symptoms, which would not persist on an empty stomach. In duodenal ulcer, on the contrary, the patient would feel better with a full stomach. Cholelithiasis produced a sudden, agonizing pain, without warning, in the upper quadrant, which usually required morphine, but disappeared as suddenly as it came. The speaker said jaundice was associated with: (1) Cholecystitis; (2) catarrhal states; (3) hepatic cancer; (4) cirrhosis; (5) cancer of biliary ducts; (6) acute yellow atrophy. Stupor was associated with acute yellow atrophy and with cirrhosis in the terminal stages. *Pancreatic carcinoma:* This had a distinct history; the jaundice advanced in imperceptible stages, due to gradual compression of the ducts, not associated with chills and fever, but with distention of the gall-bladder. *Peptic ulcer:* In 75 per cent. of cases there was interference with emptying of the stomach, and pain related to ingestion of food. There was chronicity and periodicity. *Gastric Cancer:* This produced cachexia, and there was obstruction and vomiting in some cases. The differentiation between ulcer and cancer lay in the periodicity of the former. The cancer cases were of three types: (1) 30 per cent. of cases were in good health and were seized with sudden gastric distress, followed by quick physiological loss, emaciation, anemia; (2) 60 per cent. of cases had had chronic gastric ulcer for years, which responded to treatment; finally they ceased to respond and went progressively downhill and died in six or eight months; (3) 10 per cent. had had a typical ulcer history, going progressively downhill, becoming cachectic, and dying without regaining any ground.

Physiological Factors Underlying Operations upon the Stomach and Duodenum.—Dr. W. WAYNE BABCOCK of Philadelphia read this paper. He said that surgeons often made gross physiological errors. How.

many men had given meat broths, thus increasing acid after abdominal operations; had had the patient sitting up in bed with ruptured varix of the leg; had raised the head in cerebral hemorrhage; had given strychnine or alcohol for shock; had administered atropine in opium poisoning; had given morphine for the delirium of uremia; had used salt solution in renal embarrassment; had prescribed a protein diet in thyrotoxicosis; had increased the difficulty in inducing ether anesthesia by telling the patient to "take deep breaths"? These were but a few of the common mistakes. Dr. Babcock said the physiology of the stomach was just beginning to be understood. Briefly it might be said that the stomach was J-shaped, the greater, vertical portion being for storage of food, and the lower portion for mixing and grinding. The food was stacked in layers, the last taken, resting near the fundus, the first taken resting near the pylorus. The layers varied in reaction. The pyloric antrum would give alkaline mucous secretion; the prepyloric area secreted pepsin and hydrochloric acid; the fundus and cardia were free from acid. The food did not actively mix so while the cardia was alkaline, the prepyloric area remained acid. That was to say this condition was found 20 minutes after a meal; one hour and a half after, the fundus had acid contents, and the antrum was alkaline from regurgitation of bile. Liquids passed readily out of the stomach. The food entered the stomach teeming with bacteria from the mouth, which was sterilized by the gastric juice, so that intestinal digestion began unhampered by bacterial contamination. The acid chyme was ejected in spurts into the duodenum, by relaxation of the sphincter, and Oddi's muscle let the fluid out of the bile duct. Secretin was formed in the duodenum and stimulated bile and pancreatic juice. When the chyme was neutralized the pylorus again relaxed, and took another spurt of chyme. There was also an ileopyloric reflex which acted like the signal of a block system. The traffic was not allowed through until the road was clear ahead (by emptying of the ileocecal valve). Leakage of the acid gastric juice into unprotected portions of the bowel caused ulceration. Thus anastomotic operations of the stomach and intestine were frequently followed by ulceration. The protective action of the bile on the stomach was being slowly appreciated. There was a reflux of alkaline bile into the stomach two hours after a meal, which served as a resting medium of the stomach. Probably nausea and vomiting was a protective mechanism, and after the stomach was coated with bile the nausea ceased. Peptic ulcers occurred in portions most exposed to chyme, and unprotected by the bile. Thus in operations which allowed of bile regurgitation, the ulcer-bearing area was protected. It was difficult to entirely neutralize the chyme, because acid producing cells would go on secreting in the presence of alkali. A continuous loss of bile was followed by dyscrasia, and such patients could not stand a second abdominal operation. In old and weak patients, therefore, the safest operation was internal drainage, by anastomosis between the stomach and gall bladder. This prevented obstruction of the biliary system and allowed of prompt wound closure. Often chronic biliary obstruction, suddenly relieved, was followed by cholemia and death. Sometimes it was not safe even to remove stones at a first operation. Internal drainage would save the patient for a second-stage operation; cholecystogastrostomy, or cholecystoduodenostomy. Care must be taken not to traumatize the tissues if the patient were very toxic. In infection of the common duct local anesthesia and a transverse incision were useful to save traumatism of the duct. In Hanot's cirrhosis with marked jaundice a patient had remained symptom-free for 3 years, after cholecystoduodenostomy. It should not be forgotten that some portions of the intestine should be fixed, and some required mesenteric attachment. The duodenum and ascending colon (the great liquid stand-pipe of the body) should be fixed, the jejunum required freedom. It had been said that "We drink with the ascending colon, we eat with the jejunum and ileum." If posed, the heavy, water laden ascending colon would drag upon the right kidney, gall bladder and upper duodenum, giving rise to renal, biliary and gastric symptoms. In conclusion, if any present had made no errors in surgery, due to unrecognized physiological

conditions, the speaker said they had his congratulations.

The Reflex Stomach from the Surgeon's Point of View.—Dr. GEORGE D. STEWART of New York City presented this communication. He said that while it was agreed that the patient is a compound of certain interrelated systems, it was never acted upon. The system primarily at fault was accused. One had heard that the thyroid was a procreative organ, but so was a good pair of legs. The stomach was the spokesman for a good many organs, and its language was either motor or secretory. Crile had recently come out with the statement that stomach chemistry was not much good from a diagnostic standpoint, and the speaker said he was glad to give it up. The motility of the stomach he thought was more important than the chemistry, because while gastric response by secretion was very interesting, it did not tell where the stimulus was coming from. The central nervous system had to do with the response, and while duodenal ulcer would make itself quickly felt by pain, ileocolic disturbance had to make trouble a long time before it would be heard. To understand reflex paths of the stomach one must understand the nerve supply, by the autonomic or vegetative nervous system which controlled the smooth muscle in general: digestion, heart, lungs—all necessary to life. This system did what the voluntary system did not—it took care of the lowest functions of animal life. It comprised the sympathetic and the parasympathetic. The vagus coming from the medulla influenced the alimentary canal, stomach, and small intestine; and the lower part of the cord sent off the pelvic nerve, controlling the bladder, rectum, and secretory glands. The sympathetic consisted of ganglia of the 2d thoracic to the 3d lumbar. The parasympathetic and sympathetic were direct antagonists, one producing motion, one inhibition. While they should be better physiologists than they were, they could get into too much complication, about the reflexes, and if they stuck to the history they would do better. Briefly, one could say that the vagus controlled the alimentary tract from the fauces to the rectum, then the cord took control of the sphincter; but, going down the tract, the nervous control became less important and the chemical action more important. The reflexes were so complicated and so interlaced in action that they might be produced at any level; they might be visceromotor, viscerotrophic, or visceroviscero, so that one must go very carefully in interpreting them. There were many conditions causing the stomach reflex, *outside of the canal*, such as diseases of the generative organs in the female, mobility of the kidney, disease of the central nervous system, toxemias, tuberculosis, syphilis, cardiovascular-renal disease; and *in the canal* there might be duodenal ulcer, cholecystitis, Meckel's diverticulum, chronic ileocecal conditions, gall-bladder disease, appendicular lesions. Thus hypermotility was associated with gallstones in 68 per cent. of cases; with duodenal ulcer in 75 per cent.; with chronic appendicitis in 55 per cent. Dr. Babcock had suggested there was a block system, and one could find traces of this at seven sphincter points, regulating the traffic; such were the pharyngeal, esophageal, pyloric, duodenojejunal, ileocecal, transverse colonic, and rectocolonic. There might be centers for each one of the sphincter points. Study of the cases diagnosed at Bellevue Hospital, with gastric symptoms, showed that all such cases gave clearly diagnostic histories, which should classify the case, so that while one should bear in mind the reflexes, one should not be confused by them. The term "reflex stomach" should be abolished from the literature, often being an excuse for laziness and inefficiency. A careful study of the history in intestinal, gall-bladder, and appendical cases would lead to correct diagnosis and avoid many reflex mistakes.

Dr. PETERSON of New York City said that he thought history taking was an art, but the interpretation of the history was a science. It behooved them to take as good a history as possible and to interpret it accurately, but not to neglect to take into consideration the reflex conditions that Dr. Stewart thought so little of.

Dr. W. D. JOHNSON of Batavia, N. Y., asked where did Dr. Babcock get all his physiology? It was not in the text-books. All the experiments recorded contained

the words "there may or may not be . . ." which gave no information at all. Of 4 000 experiments quoted in one book, less than 40 were productive, so that one had to go slowly in applying these experiments to human physiology. Dr. Babcock had that rare faculty, the scientific imagination, and he was able to project it. Dr. Johnson said he was glad some one had the courage to try cholecystoduodenostomy. The man of 30 years ago was proud of his knowledge, and they must be proud of theirs of today for it was the only chance they would have. Thirty years hence they would be ashamed of what was believed today. When they remembered the postoperative treatment of 30 years ago they recalled that the patient thirsted and was given warm water in a teaspoon; he was in agony and was grugged morphine. The medicine of that day was tinctured with the theology of that day, everything that man liked or wanted was bad for him. Probably some of the accepted theories of today were equally fallacious. There had long been an idea that bile-bathed wounds did well. Dr. Babcock had said that the fluids of the upper digestive tract were sterile. Charles Mayo had said that gastroenterostomy was like tile drainage, it kept the stomach sweet. Probably many of these surgical conditions of the upper abdomen were the penalty man had paid for the upright position.

Dr. E. M. STANTON, Schenectady, N. Y., said he thought stomach reflexes were associated with many different conditions, such as biliary colic, renal colic, etc., and many patients had subjective symptoms referred to the gastrointestinal tract, the chief of which was vomiting. Notwithstanding the enormous number of laboratory tests, and the availability of the x-ray, the important fundamental thing was the careful clinical history of the case; with that, additional data might be of great service; without it, they might be dangerous and misleading. The successful interpretation of the history lay in the ability to pick out the relevant from the irrelevant. He had kept careful clinical records for 14 years, and could say that there had not been a single case cured by himself or another surgeon in which there was not some symptom in the clinical history which pointed clearly to the diagnosis. Many errors crept in by reporting cases two or three months after operation. One could take almost any class of indigestion, and do any practical operation in the bowel and the patient would be benefited, either by psychological cure, by operative rest cure, or some other factor, but take the case years afterwards, and one could say something more definite. The really cured cases were clean cut.

Dr. E. W. LEE of New York City, said they were likely to stuff themselves at this banquet of learning, and to hear more than they could digest. The amount of things to be considered in a diagnosis was confusing. He never made a mistake in diagnosing a patient whom he saw alone in his office, but when he went to the hospital and several men saw him the speaker began to wonder what was the matter with him. In other words, the history depended upon the man who took it. The question was, were they going to let the patient tell his story, or to question him and let him say what he thought he was expected to say? The prognosis depended upon the diagnosis. This depended upon the history. Andy McCosh got a case in which the history made it uncertain whether a brain tumor was on the right side or the left, so he opened both sides. Perhaps Dr. Stewart would tell what number of diagnoses were made at Bellevue Hospital which were confirmed by postmortem examination.

Dr. C. G. HEYD, in closing, said he wanted to emphasize one point, and that was that if one had 100 patients, with a carefully made history, and had another series of 100, in which the x-ray and laboratory tests were carefully made, then submitted these data to an expert, the diagnoses based on histories would have a much higher percentage of correctness. He was grateful to Dr. Babcock for clearing up several points, and to Dr. Stewart for amplifying them.

Dr. G. D. STEWART, in closing, said that they were closely in accord in the fact that history and judgment based on observation were the important things in making a diagnosis. In regard to Dr. Babcock's paper, and his own, he recalled what the devil said when he saw the revised version of the Bible, "The plot is the

same." He believed that in the end they were coming back to some form of pyloroplasty, so as not to disturb the chemistry of the organs. One might draw that inference from the studies of Dr. Babcock. In time one should find some way of curing these people without operating. Dr. Johnson was a philosopher: many things would doubtless be discarded before some of them were gone. The progress of science was not static but dynamic. The Principia of Newton was being assailed in New York City today, and there was nothing permanent but beauty, and love, and Santa Claus.

Gastroduodenostomy, versus Posterior Gastroenterostomy, in the Treatment of Duodenal Ulcer.—Dr. W. W. PERCY of Rochester, N. Y., made this presentation. The speaker asked whether the technique of gastroenterostomy were really justified by its results. The operation of Finney, called pyloroplasty, was really gastropyloroduodenostomy. The ideal method was to do away with the pathological condition, without disturbing the normal relationships and normal secretions. The degree of relief to the patient must be considered, as well as the permanency of cure. The aim was to get the stomach to functionate with as little effort as possible, by making an opening for the food to pass out. With an obstructed pylorus nature had to make a greater effort to evacuate the food, thus causing the pathology. The opening of gastroduodenostomy gave free drainage to the stomach and lessened the acid. Nature tried to open the pylorus even when the gastroenterostomy was functioning well. The bile and duodenal content assisted in reducing acidity and healing of the ulcer. The technique of gastroduodenostomy was supposed to be more difficult than that of gastroenterostomy, but that was only because men were less familiar with it. When practised it was easier, and the statistics were better, with fewer recurrences and low mortality. A slight modification of the Finney technique had been used.

Dr. JOHN E. JENNINGS of Brooklyn, said that the treatment of gastric ulcer would be ideal if we could remove the cause, which we did not know and for which we were groping. They might correct the deformity, which was usually at the pylorus. In the older cases with scar formation he thought some form of pyloroplasty preferable, not necessarily standardized, but one in which the punishment would fit the crime. Plastic work would be done more and more, though it was the substitution of one form of pathology for another. In gall-bladder cases it was foolish to do gastroenterostomy, because infection was pouring into the common duct. The diagnosis was really made on opening the abdomen although the history gave one a suspicion.

Dr. W. W. BABCOCK of Philadelphia said he was glad to hear Dr. Percy contrast pyloroplasty with gastroenterostomy. Many of them were thinking along the same lines. Dr. Jennings was an opportunist, and he had been impressed the same way, that was, that on opening the abdomen, and dealing with adhesions one must treat the deformity as each case required. One did not get one set form of operation. When one got scar tissue the free mucosa above slipped down and one could do pyloroplasty, which gave good cosmetic and functional results.

Dr. W. W. PERCY, in closing, said that Finney had laid stress on the opening of the stomach and duodenum, which gave splendid access to the ulcer area and made possible its treatment. The object of this paper was to call attention to the fact that personally the speaker believed surgeons were doing gastroenterostomy as a routine measure without thinking of a better procedure. One should reconsider the advisability of using this routine procedure which produced so many poor results.

JOINT MEETING WITH SECTION ON NEUROLOGY AND PSYCHIATRY.

Wednesday Afternoon.

DR. MICHAEL OSNATO of NEW YORK in the Chair.

The Accomplishments of Intracranial Surgery.—Dr. CHARLES H. FRAZIER of Philadelphia made this presentation. He said that local anesthesia should be deprecated in cranial surgery, as it was too trying for

surgeon and patient. In the war, cranial defects were a common operation, and experience taught a return to the original technique of pericranial grafts. *Brain abscess:* Otolologists usually performed operations on these lesions, and often were responsible for their occurrence if middle-ear infection were neglected. To detect these lesions early two points were necessary: (1) intimate knowledge of the parts concerned; (2) intimate study of the literature as to verified point of origin. The LeMaitre technique was very useful. A fine exploratory needle was first introduced, then gradually fine drainage tubes were inserted to take its place, ending with drainage tubes of larger caliber. This protected the meninges and subarachnoid space with a wall of adhesions, and secondary meningitis did not occur. In *Pituitary body disturbance*, loss of vision, headache, and pressure phenomena occurred. The question was how best to restore or conserve vision. One must determine how far the lesion had progressed, whether or not beyond the sella. Two routes were favored, the transfrontal route and the sphenoidal route. The latter gave a lower mortality but the former exposed the process better. X-ray or radium, combined with decompression gave the best results in pituitary lesions. In *Trigeminal neuralgia*, the picture was usually clear cut, but there might be some atypical cases. One should be sure of the diagnosis before resorting to radical operation. Sometimes coacination of the phenolpalatine ganglion, by the Sluder technique, was indicated. Some of these obscure neuralgias had origin in the sympathetic system, which bordered on the trigeminal. Either the motor or the sensory root could be sacrificed, as occasion demanded. *Brain tumors* were of many kinds, and varied as to structure and location. The epitheliomata differed from gliomata for instance, and location might be tentorial, subtentorial, cerebellar, or of the acoustic roots. A technique had been tried of injection of air into the ventricles to see if they were dilated or collapsed. Another plan was that of intravenous injection of saturated salt solution to relieve pressure by reducing brain volume. Two points were important; reduction of pressure and prevention of hemorrhage. Autotransfusion of 600 c.c. of titrated blood would often prevent untoward reaction after operation. The removal of this amount from a healthy person previous to operation made little difference, and it could be kept in a refrigerator until needed. Closure of the defect could be done with thin scale-like layers of periosteum of the outer table.

Dr. A. W. ADSON of Rochester, Minn., said that it was a pleasure to listen to this paper which had called attention to significant surgical problems. The question of transfrontal, versus transsphenoidal operative route was a difficult one. The transfrontal had a higher mortality; the transsphenoidal route, combined with radium offered more than any other type of surgery. Radium would have a definite field in brain surgery. In the pituitary lesions there was a percentage of hypo cases, as well as aramegalics. They were now operating on the cases with hemianopsia.

Dr. CHARLES A. ELSBERG of New York said that Dr. Frazier had mentioned the points of chief interest in brain surgery. In regard to pituitary tumors and the decompression operation, as years had gone on he had done fewer and fewer decompression operations, and then only as part of the operation for removal of the tumor. One was often asked to do decompression for patients in stupor, but it would never relieve such patients; it often made them worse; in fact they never woke up from the operation. In the subtemporal decompressions the patient would be left with a huge bump on the side of the head and would not thank the surgeon for it. In the infiltrating growths, decompression would not benefit eye symptoms, or relieve hemorrhage or hemiparesis. One could accomplish more by permanent drainage of the ventricles, because of the ventricular distention in tentorial tumors. Many ventriculograms had been done but the ideal had not been reached, and would not be, until they found a fluid which could be diffused all through the ventricle. At present it was necessary to empty the ventricles entirely, and substitute air. This was a dangerous procedure and great care was needed; meanwhile they should look for something better.

Dr. FRAZIER, in closing, said he was glad Dr. Adson advised radium in pituitary lesions. He thought there was a future for that treatment. The pituitary differed from the thyroid, but with adjustment of technique, radiation could be used. Dr. Elsberg had mentioned the limitations of cerebral decompression. It was of use where there was no growth, or in early cases, but in advanced cases removal of the tumor was essential.

Remarks on Spinal Cord Surgery.—Dr. CHARLES A. ELSBERG of New York City presented this topic. He said that he would not speak of operative procedure, so much as of symptomatology. Pain in spinal cord disease was very significant, and led to many diagnostic mistakes. The gastric crises of tabes had been mistaken for peptic ulcer, and many abdominal symptoms occurring in spinal cord disease were not correctly recognized. This question was of interest to the internist and the surgeon as well as to the neurologist. Patients were now being seen and operated upon earlier for spinal tumor, and brain tumors were recognized before the patient got choked disks. Still diagnostic errors were made. Without criticism, the following cases were reported: (1) a young girl, supposed to have appendicitis, with high temperature and rigid rectus muscle. Examination showed extreme skin tenderness (not deep) in the lower right quadrant. The patient was found to be suffering from cord pressure from an old Pott's disease. (2) A woman, 50, had iliac pain. The appendix was removed; the kidney was sewn up; the ureters were catheterized. As she still complained of pain, she was labeled "hysterical," and by and by found her way to a neurologist. Examination by the latter discovered exaggerated ankle reflexes, and slight disturbance of the plantar surface of the feet. Spinal cord tumor was suspected, and the patient was operated on. A lower dorsal tumor was removed, and the patient got well. (3) A woman with pain in the right hypochondrium, a suspected cholelithiasis case, was operated on and a few stones were removed, without relief of the symptoms; the appendix was then removed, without improvement; then a right inguinal hernia was treated without result. The woman was finally considered "neurasthenic" and sent to a neurologist. Slight neurological signs were found suggestive of spinal tumor, and at operation three small tumors were found lying on three nerve roots. Removal caused complete recovery. (4) A case of coccygeal and rectal pain in which there were various operations on the rectum without result, and which proved to be a tumor of the roots of the cauda equina. (5) Man with prostatic symptoms and cystitis, due to tumor in front of the cord. (6) Young woman, 22, just married, difficulty in urination, which was thought to be due to a small fibroid. An abdominal hysterectomy was done, but later it was discovered that there was disturbance of sensation over the rectus. A typical neuritis of the cauda equina roots was found, which yielded to careful rubbing of the roots with bichloride. (7) A woman sent to the neurological institute for bladder symptoms, who was found to have varicose veins in the spinal canal, causing pressure; removal cured the symptoms. These cases pointed to the necessity of thinking of the spinal cord in pains of obscure origin, and of making at least a superficial spinal examination.

Dr. CHARLES H. FRAZIER of Philadelphia said that these cases emphasized the necessity of watchfulness for typical as well as atypical cases. One should do exploratory operation where the lesions could not be accounted for in other ways. In answer to a question, Dr. Frazier said that there was scarcely an appreciable amount of decompression from opening one layer. In pretentorial lesions they tried not to lower the pressure. There was a difference between the pretentorial and subtentorial types.

Dr. CHARLES A. ELSBERG, in closing, said that changes in the cerebrospinal fluid, in tumors, were due to pressure. The nature of the pains varied exceedingly, sometimes being intermittent, sometimes constant. When the tumor pressed upon the nerve, in any position of the patient, there was pain. There was no particular characteristic of the pain, as regards time or location.

The Surgical Treatment of Brachial Plexus Injuries.—

Dr. A. W. ADSON of Rochester, Minn., presented this communication. These lesions might vary from involvement of one muscle to all, and from slight compression of one nerve to complete laceration of the entire group of the sheath and fasciculi, with evulsion of the nerves. Patients were divided into three groups: (1) under 2 years, (2) between 2 and 5 years, (3) over 5 years. Two views were held by two schools as to injury to the brachial plexus; one holding it to be purely nerve injury; the other to be an injury of the shoulder joint, producing laceration of the capsule, by effusion of blood and formation of scar tissue. One point was shown, that if the orthopedic lesion were reduced the paralysis disappeared. Operation, however, did not produce perfect results. Often in later life the individuals had atrophy and wrist drop. The relation to long and difficult labor was definite. Of 45 patients, 27 were forceps deliveries, with 3 breech presentations, thus showing there was traction on the head before birth. Other cases in adults were caused by war wounds, and stab wounds in the arm. The greatest amount of recovery took place in young children under 2; these recovered 56 per cent. of function. It would seem in older cases that exploratory operation might be done, but surgery held out very little hope in brachial plexus cases.

Dr. ALFRED S. TAYLOR of New York said that he was interested in the statistics, but he differed frankly from the views of the speaker. He felt that statistics were misleading because though he had operated on a number of cases, no two were just alike. In experimental work, different men got different results. His own work was confined to new born infants. It would be easy to reproduce the lesions found at this age. In one case of difficult labor, with the head not engaged, and a deformed pelvis he was obliged to make traction on the shoulder and felt the right brachial plexus give way, and there was a birth palsy lesion. The child died two hours later, and they had the body for examination. After hardening, they found the typical lesions described in the communication of Park and Taylor, so that traction was felt to be one of the chief factors. The lesion would be one of the 6th cervical, in 30 per cent. In regard to age, most cases showed improvement under two years. If it occurred after 5 it was due to neurogenesis. The posterior dislocation of the shoulder doubtless occurred later, as a consequence of the birth lesion. Of 30,000 cases at the Lying-in Hospital, Dr. Painter never saw one of posterior shoulder dislocation. In adult cases the results of treatment were not as good as in children. The best results were obtained from putting the arm in as good a position as possible at the time of birth, giving the traumatized nerves opportunity for recovery.

Dr. A. W. ADSON, in closing, said that he had presented the figures as they stood, without attempting to draw conclusions from them, nor to advocate any particular type of operation. His own results were had in adult cases. He thought statistics would help them to come to some sort of definite conclusion as to the future of the patients, by showing which result was good and which was bad. These cases were more or less indefinite, and no doubt some of them were not surgical at all. Sometimes tendon transplantation was indicated, sometimes arthrodesis.

Cervical Ribs, With Special Reference to the Surgical Treatment.—Dr. ALFRED S. TAYLOR of New York City made this presentation. He said that this deformity occurred in one in 300 cases, was usually bilateral, and varied greatly in size, from an exaggeration of the transverse process to a fully developed rib. The trouble was occasioned by pressure on the nerves, 7th and 8th cervical and first dorsal, passing over the blade-like edge of the rib. In round ribs there were not so many symptoms. The type of disturbances varied: there was sometimes sensory disturbance of the ulnar distribution, sometimes circulatory disturbance with formation of aneurysm. Thrombosis of the artery and gangrene might occur. Complications might be myositis of the neck muscles and neuritis. The treatment was operative, but care must be taken not to do damage to the brachial plexus, or the consequences would be serious. There were three types of operative approach: (1) anteriorly, getting at the rib in front of the plexus; (2) lateral exposure; (3) the posterior route, going to

the side of the spinous processes, through the trapezius. In this it is difficult to get out the head and neck of the rib. The muscular and aponeurotic attachments of the rib must be removed. If periosteum were left there would be a recurrence. The consideration of the cosmetic result was important.

Dr. BYRON STOOKEY of New York City said that while the x-ray showed an apparently normal head there were symptoms of the 8th thoracic. There were two distinct types of plexuses: the first thoracic and the 2d thoracic. In the plexus of higher origin, the development of costal structure, by pressure, prevented formation of a cervical rib. By implication of fibers within the thoracic plexus and irritation of the sympathetic fibers within the nerve trunks, vascular changes were produced resulting in abnormalities.

The Surgical Problem of Nerve Defects.—Dr. BYRON STOOKEY of New York City read this paper. He said that the first operations on nerve tissues were by bridging the gap by catgut strands, or by turning down a flap of the nerve. These were of no use, and simply created scar tissue. In very rare cases the latter became a nerve transplant, but usually the operation failed. Another method was nerve transposition, passing the nerve through a course shorter than normal; thus by putting the ulnar nerve in front of the elbow, or the median in the pronator teres, a shorter route was acquired. Nerve stretching was another method which was useful, but had its limitations, for if stretched too far the fibers ruptured and small hemorrhages occurred within the nerve; the anterior horn cells showed chromatolysis and the nerve fibers degenerated in consequence. A nerve graft, with multiple fibers had to be used to bridge too large a gap. This was according to the experimental work of Huber, and clinically some cases showed recovery. Elsberg had reported one success, Frazier one, Gusset four, and Joyce, in England, several. Lantern slides were shown to illustrate the distribution of blood vessels in the neurium and perineurium, and the lack of elastic tissue in the peripheral nerves preventing their stretching. In the graft large fibers should be avoided, as the central portion had fewer neuraxons than the periphery,—probably a matter of nutrition, and a large graft was not of much use.

Dr. A. W. ADSON of Rochester, Minn., said that overstretching of the nerve was dangerous. In trigeminal neuralgia one relieved the pain by peripheral evulsion. He said he had not been successful with nerve grafting. One must not forget the value of orthopedic measures, such as tendon transference and arthrodesis. Functional results were what the patient wanted, rather than indefinite waiting.

Dr. ALFRED S. TAYLOR of New York said that he did not agree with Dr. Stookey entirely. Somebody could always report a successful case of a method which had been condemned. There were always these exceptional results. One should, however, use the method that would give 100 per cent. results. He agreed with Dr. Adson that the results in peripheral nerve grafting were unfavorable.

Dr. B. S. STOOKEY, in closing, said that if the sutures were not tied with the precise amount of tension, and the ends apposed, the result was poor. One-eighth or one-sixteenth of an inch off spoilt the result. One might bring the graft behind the cross section and away from the nerve. The technique was not very difficult, but it had to be very precise or the neuraxes would not go through. In regard to Dr. Taylor's point, the speaker said he knew one case in which the nerve-flap operation had been successful.

Thursday, May 5—Third Day.

Synergistic Analgesia.—Dr. JAMES T. GWATHMEY of New York presented this topic. He said that in the endeavor to find a substance that would improve the injection of morphine he found that magnesium sulphate, 25 per cent., chemically pure, combined with morphine produced a very reliable synergistic analgesic. The perception of pain was dulled by doses that hardly affected ordinary sensibility. The mechanism was probably that the magnesium held the morphine in contact with the central nervous system. The majority of patients preferred to be unconscious during an operation, and to know nothing about it. Local

anesthetics should be used to quiet the cutaneous nerves. In morphine and magnesium sulphate anesthesia the breathing was like natural, but prolonged, sleep. Nausea and vomiting were reduced to a minimum, the waking was pleasant and there were no gas pains. The amount of morphine required was a minimum. Patients were carried through the pain zone and woke comfortable. Appetite was better and there was a shortening of convalescence.

Anesthesia: Its Place in the Practice of Medicine.—

Dr. J. J. BUETTNER of Syracuse made this presentation. He said that anesthesia was concerned with life and death, more so than the scalpel. The anesthetist should be a consultant capable of preparing the patient properly and of giving the anesthetic best suited to him. Light anesthetic often saved the patient. Physicians should have special instruction and training in the art of anesthesia, and the anesthetist and surgeon should be in close cooperation. The extra trouble taken in careful anesthesia was compensated for by the easy and pleasant convalescence of the patient.

Anesthesia With Nitroxxygenated Ether Vapor.—Dr. ADOLPH F. ERDMAN of Brooklyn made this presentation. He advocated the use of nitrous oxide for carrying other agents. Oxygen was the corrector and ether the base. The machine ran itself, and the apparatus was portable, the dosage was automatically controlled. The closed method was not always used, and patients were often allowed to rebreathe. The relationship of oxygen and CO₂ was important. The patients received a gradually increasing volume of straight gas, oxygen was begun as needed, and ether turned on when necessary. The method was easy and direct and very useful in the speaker's hands.

Dr. CHARLES H. SANFORD of New York City said he had used this method for some years with great satisfaction; they had the best kind of conveyor of vapor (chloroform or ether vapor), with a reliable apparatus which gave constant dosage which could be regulated to keep the patient under anesthesia for several hours. He thought the closed method was to be preferred, the dosage was more constant, and regular proportions of nitrous oxide and oxygen could be given. He did not believe ether would ever go out of use.

Dr. ADRIAN V. S. LAMBERT of New York said he wished to bear testimony to the impressions he had gained by the use of magnesium sulphate in connection with morphine in anesthesia. He was quite convinced that that combination gave a greater degree of relaxation for abdominal work than nitrous oxide anesthesia alone, with prolongation of analgesia. Less anesthetic was required for intraabdominal operations. In one instance where the patient recovered from an unsuccessful attempt to remove a cord tumor of the sacral region, and suffered reflex action of the lower extremities, the action of morphine alone was without much effect, but combined with magnesium sulphate, it caused 18 hours cessation of the reflex movement. The administration lately had consisted of a 5 per cent. solution, 300 c.c. subcutaneously as a hypodermoclysis, which had procured uniform results.

Dr. GORDON of Philadelphia reported 100 cases of synergistic analgesia at the University of Pennsylvania. One half hour before operation they gave $\frac{1}{4}$ grain morphine and 25 drops magnesium sulphate solution; 15 minutes later, another dose, and 15 minutes later 1 oz. ether with olive oil and paraldehyde, per rectum. The blood pressure was not changed and post-operative vomiting was nil.

Dr. J. J. BUETTNER, in closing, said he had used pantopan, rather than morphine, and vomiting was the exception rather than the rule. In nitrous oxide anesthesia he gave straight gas and oxygen, very little ether was used.

Dr. J. T. GWATHMEY, in closing, said he got splendid results with rectal anesthesia, and had reduced ether to a vanishing point,—one or two oz. per rectum.

Painless, Non-disseminating, Chemical Removal of Inoperable Cancer of the Breast and Metastasized Axillary Lymph Nodes. With Report of the First Forty Cases, 1898-1920.—Dr. CHARLES W. STROBELLI of New York presented this communication. His report covered 215 cases, with 90 deaths, and 63 nonrecurrences. This compared favorably with approximately 50 per cent. of recurrences after surgical removals in operable

cases. His cases were advanced inoperable ones. The reason for surgical recurrences was that showers of infected cells would fall into the vascular stream. In chemical removal the dissemination was nil. Arsenious acid was first used as a cauterizing agent in the first experimental case, but since then zinc oxid, in concentrated solution, and in a paste form was used, thickened with flour so that it could be spread on. The devitalized tissue could be easily and painlessly removed, until the whole breast was bared to the chest wall. Skin grafts were then sewn in the form of Thiersch grafts. No pain was felt if the chemical was confined to the carcinomatous areas. Such growths as scirrhous, fibrocarcinoma, adenocarcinoma, and some carcinoma had been completely removed. Thirty-two patients had died in from two to eight years after removal, generally in coma. The author was contemplating the application of this method to operable early cases, hoping to obtain better results than in surgical removal.

Dr. WM. S. STONE of New York said that this paper was a very important contribution, in regard to the fact that it provided an additional resource in inoperable cases. The first treatment of cancer was by quacks, as surgeons did not have the courage to attempt it. The chemical treatment fell into disuse when modern surgery came into being. The scar, however, after the chemical method was a much better one, and local recurrences were fewer. Dr. Ewing thought that the work had a good theoretical basis in the use of zinc chloride, on account of the excessive leucocytic exudation, in which vagrant cancer cells were destroyed. In other words, a protective layer was thrown out. The x-rays and radium produced lymphocytic exudation, and heat produced dilatation of the vessels. It must be remembered that Dr. Strobell had taken the riff-raff, cases that no surgeon would touch, and he had obtained results comparable with average surgical statistics. The skin grafts had been uniformly successful. If he had merely succeeded in making the patient comfortable for a year or two more of life, he had done well. The twilight sleep was used for taking off the skin.

Dr. L. DUNCAN BULKLEY of New York said that he considered this method a wonderful addition to the therapy of cancer. They had not allowed a knife to touch these cases for some years. It would seem feasible to use this method in early cases, as the scar was much better than the surgical one and recurrences fewer. The method was painless and the skin grafts took well. He was in favor of chemical removal. He believed it was a great advance in the local treatment of cancer. The paste was mixed with charcoal, so as to show the edge of the application, and not to cover the unaffected skin. Removal of the sloughs was painless.

Dr. STROBELL, in closing, said that the scopalamine-morphine treatment added much to the ease and painlessness of this method. The patients went to sleep and by the morning had forgotten about the operation. Removal of devitalized tissue caused no pain. Scopalamine was also useful in minor surgical operations and painful examinations. The patient remembered nothing of what had taken place.

JOINT MEETING WITH THE SECTION ON MEDICINE.

Foreign Proteins.—Dr. DAVID M. COWIE of Ann Arbor, Mich., read this paper. He said that a distinguished anatomist of the last century said to his students, "Beware of making anatomical discoveries." The field had already been reaped; next came the gleaners, next, waddling, came the geese. The speaker added, "Gentlemen, we are the geese." What, he asked, was the nature of nonspecific proteins? Men were waddling here and there picking up grains of information, but they did not know the mechanism. There were many infectious processes running a definite course and terminating in cure. There were others tending to chronicity and bodily abnormality. Arthritis was one of these. One should be interested in potential disease and attack arthritis in its potential stages. In this disease cure was not so good as prevention. In regard to foreign protein, its intravenous injection caused changes in the blood; leucopenia occurred in a few minutes, probably by positive chemotaxis, and taking of leucocytes from the general to the

capillary circulation. Then there occurred a hyperleucocytosis with formation of new cells, and the leucocytes were carried to some part of the body. There was increase of immunological products under injection of the foreign protein—not the bacterial immunoproductions, but those of general body resistance, such as lipases and cytases. The chemical content of the blood was not changed, although some workers had found change in amino-acid nitrogen and urea nitrogen in anaphylactic shock. The speaker did not think that the protein paroxysm was anaphylactic; it was an entirely different form of reaction. The foreign protein merely mobilized the immunological products. Foreign protein reactions were not constant, and while they caused results, did not induce permanent improvement. In furunculosis, gonorrheal vaginitis, iritis, and corneal ulcers, there was marked result. In chorea 61 per cent. of the attacks were definitely stopped. The question was, what would have happened if one had let the patient alone? Did the primary rest period do the work? In arthritis there were definite structural changes. The attacks were benefited by foreign protein therapy. This was true in inflammatory cases without cardiac involvement, and in subacute cases. The dosage that had been used was one of 500 million killed typhoid bacilli, as the maximal dose. Cardiac conditions and hyperthyroidism were contraindications. Nephritis had never been caused by this therapy. In one case, an infant with aplastic anemia, there was a good response and the blood picture was improved.

Dietetic Treatment of Arthritis, With Special Relation to Maximum Fat Feeding.—Dr. FLOYD R. WRIGHT of Clifton Springs, N. Y., read this paper. He said that diet was important in chronic arthritis and needless restriction of diet increased the disease. In the acute cases the diet was to be entirely different. In the chronic type one must maintain the patient's strength. Osler advised a full nitrogen diet. Pemberton found that meat could be ingested with benefit but that there was a lowered sugar tolerance in proportion to the arthritic process. The blood sugar chemistry showed difficulty in handling carbohydrates. Some food must therefore be used to compensate for lack of carbohydrates. Fats must be substituted in the diet, in a proportion of 10 per cent. protein, 10 per cent. carbohydrates, 80 per cent. fats. The basal requirement of the patient must be found and weight maintained; 80 per cent. fat might be found high in some cases, but 70 per cent. could be well tolerated.

Treatment of Arthritis by Drugs.—Dr. SAMUEL W. LAMBERT of New York City read this paper. He stated that chronic arthritis (excluding tuberculosis, lues, and gonorrhea) was usually of streptococcal origin, and was a chronic disease with acute exacerbation. There were general systemic reactions with the attack. The urine contained more acid. The urinalysis and the blood chemistry were not always parallel, sometimes one, sometimes the other showed higher uric acid and glucose. The origin of infection might be the pelvis or the alimentary canal. Probably secondary infection of the colon played an important part. The primary source of infection (teeth, tonsils, gall-bladder, male or female pelvis, etc.) must be treated, and the intestinal infection controlled. Drugs useful for intestinal disinfection were phenol combination with beta-naphthol, salicylic acid, or salol. Diverticula of the intestine were fruitful sources of infection. These could be disinfected with bismuth subcarbonate, or cerium oxalate. The former was a heavy, neutral powder, nonconstipating. One to four teaspoons could be given by mouth or rectum. The juice of three to six lemons a day, diluted in water, with sodium bicarbonate, was very valuable. Treatment of the joints was by aspirin, in 40 grain doses, or salicylates in 60 grain doses. The coal-tar products relieved pain. Lead acetate dressings were helpful. Diet included restriction of purins and carbohydrates, but otherwise maintaining nutrition. In regard to specific vaccines and serums, their efficacy was doubtful. Sterilized milk injections often gave better results. The reaction to the foreign protein was nonspecific. This disease had no relation to the modern fetish of medicine, the endocrine system. There seemed to be no reason for giving injections which produced a chemical typhoid fever or chemical intestinal toxemia, when the patient was already burdened with the toxins of arthritis.

Special Treatment of Arthritis.—Dr. CLARENCE E. COON of Syracuse, read this paper. He said that the profession lacked exact knowledge of the metabolic process in this disease, and did not know whether it was the action of slow poison coming from the individual himself, whether it was ductless gland disturbance, or absorption of infection. One must search for a reason why irritant poison produced symptoms in one person and not in another. Nomenclature of disease did not help the patient, and all types of arthritis might be due to some underlying cause. Treatment might be preventive or palliative; the first was most important. One heard about cases that responded to removal of teeth, tonsils, etc., but not so much about cases that did not respond, or why some cases got neuritis or chorea, and not others. Was the digestive tract at fault? Patients often presented digestive symptoms. Decomposition of food in the bowel might pass on toxins to the circulation. The intestinal tract might be the most prolific cause of arthritis. Perhaps one should be able to isolate a toxin from the bowel which would produce arthritis, and removal of which would control the disease. Sometimes treatment produced spectacular results in arthritis, sometimes very poor results, and in any case one must do what one could to relieve pain and prevent deformity. Thus the wearing of a rigid corset in spondylitis, or an abdominal support in viscerotopis. The knees could be helped by preventing extremes of motion. The metatarsal arch could be supported. The lack of appreciation of deformities was often seen, and early treatment might mean much comfort to the patient and increased function in succeeding years.

Dr. R. GARFIELD SNYDER of New York said that he had done considerable work with foreign protein injection, either intravenously or subcutaneously. The men who give specific vaccines never checked up results, to find out whether nonspecific injections would have produced the same reactions. All proteins had specific and nonspecific reactions, the latter probably the most important. In the case of milk injections one got an enormous amount of protein in 4 c.c., but to produce beneficial result, one must get a reaction with chills and fever. The nonspecific protein he had used was dead typhoid bacilli; he had never seen bad results from the toxicity. There was some loss of weight, but one gave a preliminary dose of castor oil, and after the vaccine the patient did not care for food for 24 hours, so one must consider this fact in the result. Almost any operation would help acute disease, no doubt because of the active purging, the rest in bed, and starvation after the anesthetic, and these factors must be considered. The difference in measuring vaccines must be considered in comparing results. Some men would shake up a bottle and guess at the number of organisms. It was always well to have vaccine tested in two different laboratories, to insure perfect sterilization. In regard to Dr. Lambert's remarks, proteose was a little less toxic than milk. The term focal infections was misleading, as often these infections were not encapsulated, and they should be called local infections. In his experience (and here he expected to meet with criticism) not one case or arrested disease had followed removal of supposed foci. He believed many teeth and tonsils were needlessly removed.

Dr. JOHN H. RICHARDS of New York said that Dr. Cowie had stated that the bactericidal power of the blood was increased by protein injections. That was contrary to his own experience with *S. viridans*. He had not tried other organisms. Dr. Cowie mentioned chorea. Dr. Richards had seen cessation of movements follow formation of embolism. In regard to the gall-bladder as an infective focus, he had never been able to recover cocci from bile, and was inclined to question infection in the gall-bladder, if there were bile in it. If the cystic duct had shut off the bile, there might be infection. He believed a large injection of foreign protein would be necessary to produce results, but had not seen any case permanently benefited by proteose, milk, or typhoid bacilli. With specific vaccine treatment, the bactericidal power of the blood was increased, though frequently foreign protein injections would remove residual symptoms. Sometimes there might be a bad effect, such as nephritis or persistent vomiting. Dr. Wright spoke of full diet in arthritis.

That was an important thing, on account of the hereditary character of the disease, with lowering of resistance of the patient to the particular type of infection. Exacerbations often accompanied some sort of distress, worry, or family trouble. He had been able to corroborate Pemberton's results as to low sugar tolerance in arthritis. He thought that the benefit resulting from dieting in arthritis was from the change in intestinal flora. *S. viridans* did not grow well in very acid or very alkaline media. Dr. Lambert spoke of uric acid retention in chronic arthritis. There was no nephritis, but a high acid content. Atophan gave relief. An important condition to combat in streptococcus infection was anemia. Dr. Lambert spoke of colonic infection. He had taken specimens from the small bowel and found streptococci. Colon irrigation would not affect that. Dr. Coon spoke of preventive therapy; children of arthritic families should be instructed in hygiene. Dr. Coon mentioned production of a toxin in the bowel, probably causative of arthritis, but it would be difficult to develop a toxin to do this. *S. viridans* was a resistant organism, not easily broken up to obtain endotoxins, and it did not produce exotoxins.

Dr. J. C. RUSHMORE of Brooklyn said that many patients came to the orthopedist after the internist had cured them. He wished to urge the importance of orthopedic measures in early stages of treatment. Relief of pain could be made by fixation and traction, so as to prevent deformity. One could treat by massage and heat, and these methods would give much relief. One might not change the process in the joint but one could clean up the periarticular tissue. Dr. Coon's suggestion of ankylosis should be a last resort, when one could not do anything more for the patients, and the solution of the problem was merely relief of pain. A great part of the work was teaching these people to correct posture and one could put them in a better position.

Dr. COON, in closing, said he was impressed with the fact that they knew nothing about the underlying cause of arthritis and he saw no reason to change his opinion. Many patients got no better in spite of all treatment.

(To be continued.)

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, Held February 25, 1921.

DR. HAROLD BAILEY IN THE CHAIR.

Familial Multiple Enchondromes Complicating Pregnancy.—Dr. SIDNEY D. JACOBSON presented this patient, an Italian, twenty-three years of age, who at the age of eight had developed a small chondroma of the wrist. This was removed. At that time she had no other tumors. Two or three years ago she was operated upon by Dr. Fowler of Brooklyn, who removed a portion of the right ilium. The tumor recurred and a year later was removed. The tumor was examined microscopically and showed pure cartilaginous tissue. While pathologically these enchondromas were benign, clinically they were malignant. About a year ago Dr. Jacobson had removed a growth from her abdominal wall. Within four months of the operation the woman became pregnant and it was found that she had metastatic deposits higher up in the abdomen. There was also a more recent one lower down. The older one of these tumors showed a softened center indicating mucoid degeneration. In this case the tumors were of the familial type. The woman's father, who was also presented, showed a characteristic bowing of the radius and ulna and a deposit on a rib. A paternal uncle was said to have the same condition. The removal of these tumors did not do much good because they continued to recur, and eventually a deposit was formed in a vital organ, causing death. This woman, pregnant for the first time, had been advised to have the pregnancy terminated. It was a question whether it was wiser to terminate the pregnancy or to remove the tumors. The tumors were large and their resection would mean the removal of a large portion of the abdominal wall, and with the uterus increasing in size there would be danger of a

large ventral hernia. Another point that had decided him in leaving the pregnancy alone was the fact that during pregnancy there was a deposit of calcium salts in the maternal body which nature removed later, and he had hoped that she might be cured in this way, since their therapy had failed. The x-ray photographs shown demonstrated that the patient had these tumors in her legs, arms, and in practically every bone in her body. Cases were on record in which an enchondroma had been known to perforate the bladder or pregnant uterus. Numerous cases had been reported in which paralysis had resulted from pressure of these tumors on a nerve, and cases of aneurysm had been reported as a result of their impingement on blood vessels, their sharp point having lacerated the fibrous coat of the vessel.

Dr. BAILEY said this case brought out one or two interesting questions. The first was whether she should be allowed to go on with her pregnancy. There was no doubt that in this tumor there were malignant tendencies. It was well known that during or immediately after pregnancy there was a rapid growth of all tumors. That had been their experience at the Memorial Hospital. A point that was both interesting and odd was that at the Memorial Hospital they had never had a case of general enchondrosi. Tumors of this type should be non-malignant. Dr. Bailey asked why this tumor showed a tendency to metastasize.

Dr. FREDERICK W. RICE stated that he had examined Dr. Jacobson's case. If the x-ray showed the pelvis free from growth he did not see why the pregnancy and labor should be affected in any way.

Dr. CHARLE B. DAVENPORT said he was interested in this case because of the family history and had made inquiries of the father, who showed the same condition. The father stated that his father and his father's mother and brother had presented the same familial peculiarity.

Chorioepithelioma.—Dr. ALFRED M. HELLMAN reported this case. He said that this condition was still rare enough, he believed, to warrant the reporting of every case. There were some unusual features about this case which made it doubly worth while studying. The growth was a heterochthonous blastomata, or a chorionic carcinoma, as it was called in England. In general it originated in the cells of another individual, and in that sense was a teratoma. But as it was composed of cells, not organs, it was a cytoma. It usually followed pregnancy, more often abortion, or a hydatid, and the primary growth was in the uterus, vagina, tubes, or ovaries, except in that unusual form which arose in men in the testes, evidently from some inclusion cells. Though chorioepithelioma was extremely malignant, spontaneous cures had been reported. Secondary growths appeared in the order of frequency as follows: Lungs, vagina, liver, spleen, kidneys, ovaries, brain, broad ligament, pleura, lymphatic glands, pancreas, heart, stomach, and lymph glands of the pelvis. The absolute diagnosis could only be made by the microscope. The case reported was that of a woman, aged fifty, who presented herself at Dr. Hellman's office, November 27, 1920. She had been married twenty-three years, had seven children, and had had several miscarriages. The youngest child was full grown. The last miscarriage was February, 1920, nine months before he saw her. She quoted her physician as saying that at that time she was four months pregnant. She had had no complete cessation of menses. After curettage at that time she bled irregularly for from four to six weeks and then stopped for two weeks. Two weeks before coming under his observation she was again curetted for severe hemorrhage. This failed to stop the bleeding. Her complaints were uncontrollable bleeding, at times slight, at times severe, and great weakness, with some loss of weight. Her systolic blood pressure was 128. Her urine was normal. The uterus was only slightly enlarged, was soft, and bleeding slightly. Dr. Hellman thought he was dealing with a cancer of the fundus, but did not lose sight of the fact that the patient might have a sloughing fibroid, or an incomplete abortion. On November 29 he performed a diagnostic curettage which was of negative value only. There was little tissue obtainable, and this showed a small, round celled infiltration and no malignancy. Despite his thorough curettage the patient continued to

bleed, and not wishing to wait for another hemorrhage, he advised hysterectomy on December 3, and performed it on the next day. A panhysterectomy was performed, and the round ligaments sutured into the vaginal wall for support. A small perforation of the fundus was found. Despite a slight infection of the abdominal wall, the patient made an uneventful recovery and was today enjoying better health than she had enjoyed for over a year. The pathologist's report stated that externally the uterus, tubes, and ovaries appear normal except for the puncture wound noted at operation. On making a longitudinal incision the uterine cavity was found filled with blood clot. In transversely incising the fundus there was a slight protrusion of a deeply seated mass not previously visible, containing yellow and dark brown spots suggesting chorioepithelioma. The growth was not over three-quarters of an inch in its greatest diameter. Microscopic sections showed chorionic villi, syncytial masses, and a large number of Langham's cells and numerous congested areas with heavy fibrin, and in places occasional mitotic figures and coagulation necroses. Along the course of the perforation were found syncytial masses, chorionic villi, Langham's cells and mitotic figures, evidently a secondary growth. The diagnosis was chorioepithelioma.

Two Cases of Extraperitoneal Rupture of the Lower Uterine Segment.—Dr. HERVEY C. WILLIAMSON reported these cases. He stated that the first case, a III-para, 32 years of age, was admitted to the Bellevue School for Midwives, December 18, 1916, expecting to be confined in January, 1917. She gave a history of having had a gynecological operation six years previously, the exact nature of which was unknown to the patient. Subsequent to delivery the uterus was found adherent to the abdominal wall. Her menstrual history was normal. She had had one long labor followed by forceps delivery, the child being still-born, and one spontaneous abortion at two and one-half months. The external and internal measurements of the pelvis were within normal range. The patient was seen on January 20, 1917, after having been in active labor more than twenty-four hours. The position was right occipital-anterior, and the cervix four fingers dilated. The membranes were ruptured and there was no fetal heart. The patient was transferred to the obstetrical department in Bellevue Hospital. She was prepared for operation and anesthetized. The cervix was dilated manually and the head perforated in the usual manner. After the solid blade of the Braun cranioclast was introduced within the cranial vault the cervix was found to be so firmly contracted about the head that the fenestrated blade could not be introduced. The Tarnier forceps was then applied with difficulty, the compression screw tightened, and the head delivered. There was some difficulty in delivering the shoulders, but clidotomy was unnecessary. After delivery a deep tear was discovered on the left side of the cervix, extending through the vaginal vault and about 9 or 10 cm. into the lower uterine segment. The tear was vertical and extraperitoneal. The placenta and membranes were removed manually and the body of the uterus packed firmly; the tear was loosely packed. The cervix was united with three interrupted sutures and the vagina packed. The patient lost only a moderate amount of blood, as the tear apparently did not traverse vessels of large caliber. The patient left the operating room in fairly good condition with a pulse rate of 130. Hypodermic injections of pituitrin 1 c.c. and ergot were given. The packing was cautiously removed twenty-four hours later and pituitrin (1 c.c.) given. The puerperium was uneventful aside from a mild abdominal distension for the first three days. The dystocia in this case was probably caused by irregular uterine retraction the result of ventrofixation.

The second patient was a X-para, 32 years of age, admitted to the Bellevue School for Midwives December 12, 1920. She expected confinement in January, 1921. She gave a history of amputation of the cervix and perineorrhaphy in September, 1915. She had given birth to four full-term children with normal labors had had three miscarriages and three abortions, all spontaneous. The pelvic measurements were within normal range. The membranes ruptured spontaneous-

ly on the day before admission. The patient was examined at home and a transverse presentation, left scapulo-posterior, was found, with the cord prolapsed and pulsating. On examination at the hospital the cord was presenting at the vulva; it was strongly pulsating. The cervix was two fingers dilated, but felt soft. When the cervix was about two-thirds dilated the left side suddenly opened into the uterine segment. The tear was vertical, about 10 cm. in length, and extraperitoneal. As there was very profuse bleeding the hand was immediately passed into the uterus and an internal podalic version and breech extraction performed. A premature living baby was delivered, but it could not be resuscitated. The placenta was immediately expressed by the Cr  de technique. The uterus, tear in the broad ligament, and the vagina were tightly packed, using about thirty-five yards of gauze. The tear was about 12 cm. in length. As the patient was in shock a hypodermoclysis of 1,000 c.c. was given. Ergot, pituitrin, camphor, and strychnine were given by hypodermic. Later a Murphy drip was employed intermittently for twenty-four hours. The patient recovered from the shock. On the following day the vaginal and a little of the uterine gauze were removed. On the second day the remaining portion was removed. On the fifth day, for no apparent reason, a hemorrhage occurred. This was controlled by massage of the fundus, ergot by mouth, and morphine by hypodermic. Nothing further happened until the nineteenth day, when a femoral phlebitis was in evidence. On the twenty-ninth day the patient complained of pain in the right chest, and on the thirty-second day of pain over the region of the spleen. The phlebitis later extended to the opposite leg and to the pelvis. Vaginal examination showed an extensive pelvic thrombophlebitis. The patient had an irregular temperature until the sixty-seventh day, when it became normal and remained so. She went home on her own responsibility on the seventy-fourth day, though there was still some edema of the lower extremities.

Dr. GEORGE W. KOSMAK said that these cases demonstrated the conservative method of handling rupture through the lower uterine segment where the peritoneal cavity was not involved. He cited three cases in which rupture of the lower uterine segment had occurred. Two of these were in tenements. Gauze packing was introduced; they were sent to the hospital, and made good recoveries. A third case occurred recently in a para II following a difficult labor. In this case there was a history of spontaneous rupture of the membranes, unaccompanied by pain. There was a breech presentation and the cervix was dilated two fingers. The liquor amnii had drained away. A No. 4 Voorhees bag was inserted without anesthesia at about 10 o'clock in the morning. In a few hours active labor pains set in and the patient was delivered without difficulty in the course of the afternoon. About two hours after delivery the patient went into shock, the placenta in the meantime having been retained. She was seen by a member of the attending staff, who attempted to deliver the placenta, but could not do so. Dr. Kosmak then made an examination and found a tear extending through the lower segment of the uterus up to the round ligament. There was no tear in the cervix. As the woman was in shock a gauze packing was introduced and hypodermoclysis given. She ran a temperature for two or three days. The temperature then subsided. An attempt had been made that afternoon to get the placenta, but it could not be found. The patient was making a complete recovery. This was simply another instance demonstrating that these cases could be treated conservatively with good results.

Dr. CHARLES GARDNER CHILDS called attention to the fact that in the first case rupture occurred because the cervix was not fully dilated, before the forceps was applied, while in the second case rupture occurred because the cervix was rapidly dilated. The second case was an example of the fact that manual dilatation was not always accomplished without danger, and sometimes was followed by very untoward results. He felt that manual dilatation was far more dangerous than instrumental dilatation.

Dr. WILLIAM E. STUDDIFORD said that, as he understood it, in the first case there was ventral fixation,

which did not allow of regular uterine contraction, and there was imperfect dilatation of the lower segment. In such cases rupture of the uterus usually occurred higher up. The second case gave the not uncommon history of a hurried effort to dilate the cervix after labor had begun. He thought one reason for this rupture was failure to recognize the relation of the fascial supports in doing the repair at the previous operation. In doing an ordinary circular amputation the fascia should be stripped free from the muscles; the muscle fibers should be brought together first and the fascia brought together over the muscle, and then one would be less likely to have a rupture in a subsequent delivery. It was observed that there was little hemorrhage in these cases. This was because the rupture did not usually involve the uterine artery. These ruptures were not accompanied by acute hemorrhage unless these vessels were involved.

A Twin Monster.—Dr. W. W. MOTT of White Plains presented a twin monster. These babies had been delivered in private practice. They were fused at the buttocks. At the time of labor a breech presentation was found and then three feet presented. The obstetrician tried to push one leg back when he found that all three legs belonged to the same body.

The Blood Picture in Normal and Abnormal Pregnancy.—Dr. WILLIAM E. CALDWELL read this paper in which he presented the results obtained from the chemical analysis of the non-protein nitrogen constituents of the blood as they were found, first, in normal pregnancy, and then in the toxemias of pregnancy and in eclampsia. As a result of more than 5,000 chemical examination carried out in the Harriman Research Laboratory they had come to regard the following nitrogen partition (per 100 c.c. of blood) as a normal blood picture in a healthy non-pregnant woman: Non-protein nitrogen, 35 mg. or less; urea nitrogen, 18 mg. or less; creatinine, 2 mg. or less; uric acid, 3 mg. or less, and the ratio of urea nitrogen to non-protein nitrogen, 50 per cent. These figures corresponded to the generally accepted standards of other investigators. A study of the blood pictures of 150 pregnant women, all of whom were clinically free from disease, with negative Wassermann reactions; systolic blood pressures under 130 mm. of mercury; urine free from albumen and casts, and all of whom went through a normal labor and puerperium were as follows: Non-protein nitrogen, 29.69; urea nitrogen, 11.51; creatinine, 1.05; uric acid, 1.73, and the ratio of urea nitrogen to non-protein nitrogen, 39 per cent. A grouping of cases according to the period of pregnancy disclosed no significant differences between the successive periods, although twelve cases in the ninth month showed a slightly higher average for non-protein nitrogen, urea nitrogen and uric acid. A comparison was made of maternal and fetal bloods at the end of labor which showed that the non-protein nitrogen, urea nitrogen, creatinine and uric acid in the two circulations at the end of labor were practically identical. He had also found in the blood of primipare, immediately following labor, an increase of uric acid, although it was not great nor was it constant. Slemmons and Bogart had found a much greater increase and suggested that the increase was the result of muscular effort during labor. The writer was disposed to regard the retention as due to the renal insufficiency that frequently accompanied long labor and multiple birth. Having established a standard blood picture for normal pregnancy, this was compared with the blood picture found in eclampsia and toxemia of pregnancy. Unfortunately our knowledge of hepatic function in terms of blood chemistry was not sufficiently advanced to permit of their taking it into consideration in studying the blood pictures of eclampsia, nevertheless in the light of this investigation blood pictures resulting from renal lesions had a clearer meaning. Analysis of the change in the blood content, both relative and absolute, of the several nitrogen waste products, had led to the belief that uric acid was the most difficult to eliminate and creatinine the easiest. The retention of waste products in the blood of eclampsia and toxemia was very much lower than in uremia and lower than in acute nephritis. The blood pictures did not correspond with any of the usual nephritis pictures, but came closer to those found in the so-called perenchymatous nephritis. The average blood

picture of thirty-four cases of eclampsia and toxemia of pregnancy was as follows: Non-protein nitrogen, 49.7; urea nitrogen, 26; creatinine, 2.17; uric acid, 6.19, and the ratio of urea nitrogen to non-protein nitrogen, 52 per cent. In this series, in every case in which there was a high retention of all the blood constituents, indicating a marked kidney insufficiency, the patient died. In some cases the kidneys were but slightly involved, as shown by the fact that the blood taken two days post-partum gave practically a normal blood picture. The significance of a high creatinine retention in denoting kidney insufficiency was well shown by these tables. Out of nine cases showing creatinine above 3 mg. as many as five died; and two afterward developed into chronic nephritis. The remaining two, when seen thirty months later, had had normal pregnancies and showed no signs of nephritis. In none of the cases that recovered did the patient show any symptoms of nephritis where the uric acid returned to normal early during convalescence. On the other hand, when the uric acid remained high throughout the obstetrical period, especially if there had been a high creatinine retention, the follow-up notes about thirty months later showed that the patient was a chronic nephritic. A question with which an obstetrician, after taking care of a case of eclampsia, was invariably confronted was whether this woman could safely go through another pregnancy, or whether future pregnancies would again endanger life. Clinically, he depended for an answer upon the rapidity with which the urine improved and the blood pressure returned to normal. If the kidneys had not been seriously injured the patient would probably not have eclampsia again. The blood pictures added to the clinical findings were of great value in making this prognosis. The blood pictures in preeclamptic conditions were of value both in prognosis and in outlining treatment. The histories in this series of eclampsias emphasized the importance of prenatal care.

Dr. W. G. LYLE stated that he had studied the blood in twenty pregnant women and in only four was there a high uric acid content. In each of these there were conditions that would account for it. The theory had been advanced that in prolonged labor the increased muscular exertion caused a rise in the uric acid. So far as he had gone he disagreed with Slemmons and Bogart that muscular contractions raised the uric acid in the blood. The non-protein nitrogen in all these cases was below 30. A comparative study of the bloods of mother and child in twelve cases showed that they were the same in every instance. If one doubted the uric acid method of Benedict one could check up the blood on the basis of the similarity between the blood of the mother and that of the child. The highest non-protein nitrogen he had found was 83. The urea nitrogen remained low even in eclampsia. The theory might be advanced that the urea and non-protein nitrogen remained low because it did not have time to become high. The patient either died or recovered before the urea nitrogen and non-protein became high. He could not subscribe to that theory, as he had seen cases of uremia in which within three or four days the non-protein nitrogen went up to 200, and hence felt that there must be some other factor concerned. Possibly it was the liver. It was well known that in cirrhosis of the liver the urea nitrogen and non-protein nitrogen were low.

Dr. S. R. BENEDICT said it was difficult to attempt a summary or any conclusions of any type from so much data without an opportunity of examining them more in detail. A few points, however, might be touched upon. This was a very important contribution and helped to complete the picture of metabolic studies reported by previous investigators. Perhaps the most striking results reported were the tendency to low protein nitrogen and urea. Such figures as three to five milligrams of urea nitrogen per 100 c.c. of blood, such as were reported here in some cases, had, he believed, not been duplicated in any other condition. It was obviously difficult to attempt an interpretation of these findings, but they suggested a line of reasoning that might be attractive. We must bear in mind that in pregnancy a condition existed in which a circulating fluid must supply both a growing and a stationary organism. A similar condition existed to a varying de-

gree in cases of cancer, and it was interesting to note that Miss Theis and Dr. Stone reported low urea and non-protein nitrogen figures for cases of rapidly growing carcinomas of the breast and uterus. If we applied a primary law of physical chemistry to the growth process we should infer that the growth of cells could be augmented by either increase in concentration of the reacting substances (food products) in their surrounding medium, or by decreasing the concentration of the products of reaction (waste products). From this standpoint, then, the lower concentration of urea in the blood in pregnancy would tend to favor growth of the fetus. The similar finding in cancer was in line with this point of view. Although Murlin and Bailey reported that the urea elimination in the urine during pregnancy was below normal, due to retention of nitrogen by the fetus which would ordinarily be eliminated as urea, this fact offered no explanation whatever of the low concentration of urea found in the blood in pregnancy. It must be that the condition of pregnancy offered a very specific stimulus to the kidney, which responded by maintaining a distinctly lower level of urea concentration in the blood than obtained under usual conditions. The study of amino-acid nitrogen in the blood of both mother and fetus should be extended. This fraction of nitrogen in the blood was probably used for tissue building, and it was interesting to note in the few studied cases reported that there was a definite increase in the animal acid content of the blood of the cord. In reference to the rise of uric acid in the blood reported for eclampsia and previously noted by certain observers during labor, it might be stated with reasonable certainty that this finding could not be explained through the increased muscular activity of the uterus, but that we must regard such uric acid accumulation in the blood as indicative of kidney insufficiency. The main problem of the intoxication in eclampsia remained unanswered. At least there was nothing in the present findings which would tell us whether the failure of the kidney at a certain stage was cause or effect of toxemia. Probably both factors were involved.

Dr. CALDWELL, in closing the discussion, stated that in one case that died autopsy revealed an acute kidney condition and a typical eclamptic liver. This case had the highest ratio of urea nitrogen to non-protein nitrogen, a ratio of 76. The cases in which there was a low ratio of urea nitrogen to non-protein nitrogen recovered, while those with a high ratio died. There was, however, not sufficient uniformity in the ratio of urea nitrogen to the total non-protein nitrogen to permit one to classify the eclamptics into groups on that ground.

Focal Infection of the Cervix with Its Relation to Systemic and Mental Diseases.—Dr. F. W. LANGSTROTH read this paper. (See page 857.)

Dr. MAURICE O. MAGID said that when he saw the title of Dr. Langstroth's paper he had assumed that the writer meant chronic endocervicitis. He regretted that he did not use that term in the title, because chronic endocervicitis was now coming to be recognized as a pathological entity. They used to speak of endometritis until it was proven that endometritis did not exist, that the changes in the endometrium were those taking place during the menstrual cycle. When Sturmdorf reported the results of his studies on chronic endocervicitis he called attention to the pathological possibilities that might accompany this local infection. There was proof in the literature that adnexal disease, such as tubal distortion and cystic disease of the ovary, had as its primal cause this focal infection. The cure for this focal infection had been described as a conical enucleation of the cervical mucosa. It was too bad Dr. Langstroth did not use the word tracheloplasty when he spoke of the operation, as he really performed the operation devised by Sturmdorf. When this operation was described by another name, many men did not immediately grasp the fact that it was really the tracheloplastic operation. If Dr. Langstroth had proven to the satisfaction of all present that systemic and mental disease might be benefited by this operation, he felt that they had just cause to disagree with the older authorities, who maintained that any repair on the cervix of women in the child-bearing period should not be attempted. Such contentions were correct if one considered the Emmet operation by which

the two raw surfaces of the lacerated cervix were sewed together. With this operation a great deal of the diseased cervical canal was retained and continued to act as a focus of infection. Sim's operation also had disadvantages. On the other hand, following the tracheloplastic operation, patients might readily conceive and there was seldom, if ever, any dystocia encountered in labor. Dr. Magid said he had a series of cases operated upon by this method in which labor had been precipitate rather than prolonged. A number of his patients who had remote disturbances in their joints were cured by the tracheloplastic operation. Dr. Magid said he was sorry to have to disagree with Dr. Studdiford, who stated that a possible cause for rupture of the lower uterine segment was the inclusion of the fascia when suturing the stump after amputation. There was no fascia under the mucous membrane covering the cervix. According to Sturm-dorf the muscle fibers were arranged spirally and did not at any point completely surround the cervix. These muscle fibers ended in the cervix in a serried succession of oblique circle segments which uncoiled when the uterus contracted. This dilated the os like the iris diaphragm of the microscope. After amputation the mechanism was disturbed because the muscle tissue in the stump was bound down in the scar, thus producing difficulty in dilatation with the possibility of rupture of the lower uterine segment.

Dr. HENRY A. COTTON of Newark emphasized the need of cooperation among the various specialists in attacking such a problem as they had tried to attack at the State Hospital at Trenton. Scarcely any medical problem could be worked out by one set of men alone. From time immemorial psychiatrists had taken care of mental cases and only when they came to a realization of how much help might be contributed from other sources did they obtain good results. Where there was infection there was no doubt that good results might be obtained by eliminating the source of infection. Dr. Cotton related the history of one girl who came to them when she was sixteen or seventeen years of age. She became better and was discharged. Six years later she returned and was under their care for two years. She was found to have an impacted molar and an infection of the tonsils following an endocervicitis. The removal of these foci of infection resulted in wonderful improvement. The girl was now doing nursing work in the hospital, something she could not have done before the removal of the foci of infection. Following the elimination of a cervical and other foci of infection he had had patients recover and remain well long enough to warrant the statement that their recovery was not merely temporary.

Dr. GORDON GIBSON agreed that focal infection had a great deal to do with systemic disease, but he could not say that it caused insanity or that its removal would cure insanity. They had not gone so far as to say that they had cured insanity, but they had grouped their cases into two general types: First, those characterized by dementia. In these they had found that no operative procedure or medical treatment helped the patient, so they had disregarded dementia precox and epilepsy, conditions in which the patients were badly deteriorated, and they confined their work to those psychoses not characterized by deterioration. It was just these cases where the removal of the teeth, tonsils, scar tissue, tumors, old adhesions, pustules, or any irritation at all might be beneficial. It was well known that in some women such irritations might give rise to nervous symptoms, and that the removal of the source of irritation would relieve the symptoms. Again, they had classified these cases in respect to attack. If they saw the patient in the first attack they knew that sooner or later there would be another attack and they had tried to ward off the next attack. They had operated upon some in the seventh attack. In those having the first attack they hoped to do as to put the patient in the best possible physical condition and thus possibly remove the exciting cause of the insanity. Then they had to watch these patients ten, fifteen, twenty years and see what happened to them; that was what they were waiting for. Of those operated upon during the first attack they had found in a large number of cases

that if there was a secondary admission the attack was milder and of shorter duration. In a series of cases operated upon in the second attack and seen in the third attack it was interesting that in at least five they had been able to increase the duration of sanity between the attacks. One must remember, however, that about 80 per cent. of these patients came from neuropathic stock and that any little disturbance or shock or toxemia or systemic disease would bring on an attack. These patients just on the borderline were easily pushed over, and if one could demonstrate pathological processes that could be removed one was justified in operating in that type of insanity, and the prognosis would depend upon the type of insanity with which one was dealing. Acute intoxications might cause a woman to become insane and if the infection was removed the woman recovered, but there was one dealing with the actual cause of insanity. Dr. Gibson stated that when he first started out with his investigations he was very enthusiastic, but after studying a thousand cases he became somewhat discouraged. One reason results were not satisfactory was that the women who went out from the hospital did not get good obstetrical care with subsequent babies. Some of them had puerperal mania, which, by the way, was a misnomer: the term puerperal psychosis would be better. Where there was an underlying neuropathic condition, pregnancy, or labor, or the puerperium might be an exciting cause of insanity and therefore better care during pregnancy, labor, and the puerperium would help in lessening the liability of these women to insanity.

Dr. LANGSTROTH, in closing the discussion, emphasized the importance of removing all the cervical endometrium up to the internal os. That was very important and in his previous papers on endocervicitis he had given credit to Dr. Sturm-dorf, describing his operation, and he had mentioned twice in the paper just read that the operation of choice was Dr. Sturm-dorf's. He had no intention of detracting from Dr. Sturm-dorf's work; quite the opposite. The operation acquired Dr. Sturm-dorf's name early; he believed many termed it a plastic conical enucleation of the cervix. He had named the condition a focal infection deliberately because he had never seen anything written as to the part played by the cervical endometrium in focal infection. He wished to put it on the same basis as infections of the tonsils and the teeth. Dr. Sturm-dorf might have called attention to that, but he felt that this work had put chronic endocervicitis on a different basis, namely, the basis of focal infection and nothing else. Furthermore, he believed that this was the first series of cases in which the attempt had been made in cooperation with other workers to benefit insanity and the neuroses, and certain cases had been helped by nothing else than the removal of this focus of infection. This was a report on focal infection and not on endocervicitis. The emphasis was laid on the removal of the focus of infection and was not a discussion of the methods of removal. In seventeen cases a complete recovery was made and so they stood. They were practically all out of the hospital. With reference to the type of insanity, he believed that practically all the cases cured were of the type which he understood did not show any destructive lesion in the brain substance. Manic depressive insanity, he understood, did not show any microscopical alteration in the brain structure. His personal explanation of the whole subject was that toxemia of whatever kind was circulating in the blood and in some cases it caused rheumatism, etc., and in some cases mental disease, and in certain types of cases removal of the focus of infection entirely cleared up the mental disease.

Dr. HENRY A. COTTON said they had a functional group, so called, of dementias, of which 77 per cent. recovered. He thought Dr. Gibson's trouble was in limiting his work and in not giving attention to teeth and tonsils as well as to cervical infections and gynecological conditions. That the removal of foci of infection had cured some of these patients and benefited others had been definitely proven. The hereditary and psychogenic factor was contributory, but the infection was primary and this fact would be recognized in a short time.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

OHIO STATE BOARD OF MEDICAL EXAMINERS.

Columbus, December 1-3, 1920.

(Concluded from page 805.)

SURGERY.

1. Describe a common fracture of the leg just above the ankle, giving physical signs and x-ray findings.
2. Describe technique of enterostomy, omitting opening and closing of abdominal wall.
3. Give indications for and against operation in ruptured ectopic pregnancy.
4. What class of patients take ether better than chloroform? What class chloroform? What class neither?
5. Name one of the chief complications of skull injury and outline procedure.
6. Describe operation for empyema of the antrum of Highmore.
7. Give surgical treatment and technique in carcinoma of breast.
8. Give indications for vaginal hysterectomy and describe operation.
9. Give surgical treatment of carbuncle.
10. Give procedure in a case of diabetic gangrene.

OBSTETRICS.

1. What interval should elapse after the birth of the child before (a) tying the cord? (b) delivering the placenta? How would you proceed in a case of retained placenta?
2. What is the significance of albuminuria in pregnancy? When is treatment indicated? Give an outline of treatment you would advise.
3. What causes predispose to hemorrhage in labor? Give prophylactic treatment.
4. Give symptoms and treatment of puerperal eclampsia.
5. Diagnose breech presentation. Enumerate some of the dangerous complications of this condition.

SPECIALTIES.

1. *Syphilology*: What is the period of incubation of syphilis? How soon thereafter do secondary manifestations appear? Name some lesions of the tertiary period.
2. *Eye*: Name some causes of corneal ulcer and give treatment.
3. *Ear*: Give diagnosis of inflammation of the mastoid cells.
4. *Nose*: Name some forms of nasal polypi and describe operation for their removal.
5. *Throat*: Give symptoms, diagnosis, and treatment of follicular pharyngitis.

ANSWERS.

SURGERY.

1. "In Pott's Fracture sudden abduction, usually combined with eversion, of the foot results in severe strain upon the internal lateral ligament, which gives way, or the base of the internal malleolus is torn off. The astragalus is at the same time driven outwards against the external malleolus, and the force is thence transferred up the fibula, which bends and breaks at some weak spot. Generally this line of fracture runs obliquely from above downwards and forwards through the malleolus; less frequently it is situated in the position originally described by Pott, viz., about three inches above the tip of the malleolus and is transverse, the upper end of the lower fragment being displaced inwards towards the tibia. The inferior interosseous tibio-fibular ligament remains intact, and hence the foot itself is merely rotated outwards and abducted, and the heel is drawn upwards, whilst the toes point downwards. If the internal lateral ligament alone is torn, the malleolus projects beneath the skin, and may, indeed, protrude through it; there is always much bruising and ecchymosis on the inner side of the ankle. If the malleolus itself is broken off, a distinct sulcus

can usually be felt between it and the lower end of the tibial shaft. In both these types the ankle-joint is necessarily laid open, and there is probably much hemorrhage into neighboring tendon sheaths." (Rose and Carless' *Manual of Surgery*.)

2. *Technique of enterostomy*. "(1) Having followed the steps of the intramuscular incision of the abdominal wall and retracted the lips of the wound, the cæcum is sought with the finger and located as a rallying-point. The site of the obstruction is then located if possible, and, if so, the first distended coil of intestine above the obstruction is caught and brought into the wound. Where the source of obstruction cannot be found, any distended coil of intestine is taken and brought forward (which will probably be a portion of the lower ileum). In bringing the gut forward into the wound, its normal relations and direction should be maintained, as far as possible—and only its convex, antimesenteric aspect should project from the wound, but this aspect should well fill the portion of the wound to be left open, and any excess of intestine from above should be returned to the cavity, that the upper part may not sag down upon the lower. (2) The excess of length of the wound is now closed from either end, either by through-and-through suturing of all layers with silkworm-gut or silk, or by layer-suturing with chromic gut. When shortened to the desired extent, in cases where the length has been excessive—or from and beginning with the first suture at either end, where the length has only been moderate—the serous and muscular coats of the intestine are included in the suture at either end of the wound, thus fixing the gut to the abdominal wall at the same time the lips of the ends of the wound are approximated. If necessary, two fixation-sutures may be applied laterally, passing through serosa and musculosa of the intestine and all the layers of the abdominal wound. (3) An elliptical area of the presenting gut is now sutured to the parietal peritoneum by a continuous or interrupted fine silk suture, passing through serous and muscular coats of the intestine, on the one hand, and peritoneum and transversalis fascia, on the other. A second row of continuous or interrupted silk or gut sutures may then be placed, uniting the skin of the abdominal wound to the serous and muscular coats of the intestine, including the free margin of the parietal peritoneum external to the elliptical suture in the presenting gut. Or the second row of sutures may simply unite the edge of the abdominal skin to the free margin of the parietal peritoneum. A union considered firmer by some may be secured by first suturing the parietal peritoneum to the skin all around the permanent opening—and then suturing the intestine to this. (4) If haste be necessary, an opening is at once made into the lumen of the gut, by a quick, controlled stab with a narrow, sharp knife and increased to the desired extent with blunt scissors (having ascertained that all the coats of the intestine have been pierced before inserting the blade of the scissors). If no haste be necessary, a delay of two or three days for union of the serous surfaces and exclusion of the abdominal cavity is preferable (operation in two stages). The intestinal contents are allowed to escape of their own accord." (Bickham's *Operative Surgery*.)

3. On the question of operation in ruptured ectopic pregnancy, Cragin gives the following rule: "If the patient is seen at the time of tubal rupture or abortion, operate and check the hemorrhage as soon as careful preparations for the operation can be made, unless the patient is in such extreme collapse that the operation in itself would probably prove fatal. In this case watch the patient carefully, noting the condition of the pulse at short intervals to see if the patient is improving or losing ground. If improving, wait and operate when the patient is in better condition. If losing ground, operate rapidly, seeking to check the hemorrhage with as little manipulation as possible, perhaps having an assistant infuse the patient during the operation, and leaving considerable warm salt solution in the abdomen when closing it."

4. The following contraindications for ether and chloroform are from Hare's *Practical Therapeutics*: "Ether should not be used by inhalation in bronchitis or acute nephritis, because of its irritant properties; in peritonitis or gastritis, because it is apt to induce vomit-

ing; in aneurysm or in the presence of marked vascular atheroma, because it may rupture a blood-vessel by raising arterial pressure; nor in diabetes, lest it produce diabetic coma; and if anemia is present and an examination of the blood shows that the hemoglobin is below 50 per cent., the use of the drug should be avoided if possible.

"Chloroform is not to be used in cases of fatty heart or dilatation of the heart, in those with a known idiosyncrasy, nor in the so-called lymphatic persons with overgrowth of lymphoid tissues, as, for example, adenoids. In the latter case it is particularly apt to cause sudden death. In valvular disease of the heart chloroform may be used with caution, although ether is preferable. Given a case of valvular disease that must be subjected to operation, the chances are bettered with an anesthetic than without it, as the pain and mental shock are worse for the heart than is the anesthetic."

5. Fracture of the skull may be complicated by rupture of and hemorrhage from the middle meningeal artery. The treatment of this hemorrhage "consists in trephining, removing the blood-clot, and stopping the bleeding. A flap is turned down, and a trephine hole made over a spot $1\frac{1}{2}$ inches above and behind the external angular process exposes the anterior branch. After the blood-clot is removed the bleeding-point is searched for and tied; if it is not seen, more bone must be clipped away. If the bleeding comes from a canal in the bone, it may be stopped with gauze, sponge, or aseptic wax. If the brain then expands, the bone may be replaced and the wound stitched up without drainage; if not, the bone must not be replaced, and the wound should be drained for twenty-four hours. The posterior branch can be reached by a hole made just below the parietal eminence." (*Aids to Surgery*.)

6. Operation for empyema of the antrum of Highmore: "Bore a gimlet-hole through the superior maxillary bone, above the canine tooth, or perforate the bone by means of a trocar. Irrigate daily with boiled water or normal salt solution. Keep the opening from contracting by inserting a small tent of iodoform gauze. In persistent cases it may be necessary to draw a tooth, break through the socket of the first or second bicuspid into the antrum, and insert a silver or hard-rubber tube, and also to perforate the antrum from the inferior meatus and keep the opening patent. In very persistent cases osteoplastic resection of a portion of the upper jaw will be demanded." (*DaCosta's Surgery*.)

7. The surgical treatment of carcinoma of the breast is its prompt and thorough removal, together with all the neighboring lymphatic glands. Halstead's operation aims to remove in one piece the entire breast and overlying skin, the costal portion of the pectoralis major, the pectoralis minor, and all the fat and glands of the axilla. The supraclavicular glands are removed in a second piece. An incision is carried through the skin and fat, and a triangular flap turned back. The costal portion of the pectoralis major is divided close to the ribs and separated from the clavicular portion, which with the overlying skin is divided up to the clavicle, exposing the apex of the axilla; these flaps are drawn upward with a retractor and separated from the underlying tissues, and the muscle further split as far as the humerus, where it is severed close to the bone. The breast, pectoralis major, and all fat are stripped from the chest wall, including the pectoralis minor, which is divided at each end, thus exposing the entire axilla, which is cleansed of fat and lymphatic glands from above and within, downward and outward, all small vessels being ligated close to the axillary vessels, which, with the nerves, should alone remain. The triangular flap of skin is drawn outward and the lateral and posterior walls of the axilla likewise cleared, the subscapular vessels being ligated, and the subscapular nerves preserved if possible. The mass is then turned inward and removed from the chest. A vertical incision is now made along the posterior margin of the sternomastoid, and the supra- and infra-clavicular fat and glands removed by dissecting from the junction of the internal jugular and subclavian veins downward and outward. The cervical wound is sutured, and the edges of the chest wound approximated by a buried purse-string suture of silk, which includes the base of the triangular flap, the apex being

spread over the axilla. The rest of the wound is covered with Thiersch's skin grafts. The axilla is not drained. The disability resulting after such an extensive operation is surprisingly slight. The entire wound may be closed in most cases by fashioning two flaps from the lower lip of the wound. A small gauze drain should always be placed in the axilla, preferably through a small incision at its posterior margin, in order to drain the large quantity of fluid which escapes from the severed lymph vessels." (*Stewart's Surgery*.)

8. The indications for vaginal hysterectomy, are: Bilateral suppurative conditions of the appendages; prolapse, cancer, pregnancy with cancer before the sixth month; certain septic conditions of the uterus; certain rare conditions which may require the ablation of a small movable uterus.

Technique of vaginal hysterectomy: "(1) The lips of the cervix are caught and drawn down with vulsella, or tenaculum-forceps—and are sutured together with strong silk (to prevent escape of contents). The silk ligatures may be left as long traction-loops. The uterus is thus drawn well down into the outlet (by forceps or loops)—while the vaginal walls are retracted downward and outward. (2) With a knife, or sharp curved scissors, an incision is made entirely around the cervix, passing through the thickness of the vaginal vault down upon the substance of the cervix. (3) With the right index, the cellular tissue plane is opened up in front (between uterus and bladder) and behind (between uterus and Douglas's cul-de-sac)—by pushing up and peeling back the tissues with the pulp of the finger always directed against the cervix, to prevent the fingers from slipping off violently in the wrong direction. This separation is done anteriorly and posteriorly—but not done laterally, where the vessels enter from the broad ligament. Posteriorly, Douglas's cul-de-sac is recognized by a slight amount of fluid present within its cup-like cavity and by the smooth surfaces gliding over each other. This is caught with forceps, drawn down and incised with sharp scissors to a slight extent, the opening being increased to the broad ligaments on each side by two fingers introduced and separated. Anteriorly, the separation is continued until the anterior vesico-uterine peritoneal fold is reached—which is recognized by its gliding surfaces—and which is drawn down with forceps and incised with sharp scissors to a limited extent—the opening being increased to the broad ligament on each side by fingers introduced and separated, guided, if necessary, by a sound in the bladder. The peritoneal cavity is thus opened in front and behind and the uterus is left hanging from the broad ligaments. (4) The broad ligaments are now tied off. The uterus is drawn well down and to the side opposite that upon which the ligature is to be passed, while the corresponding vaginal wall is retracted. The left index-finger is passed in through the posterior opening behind the broad ligament and near the cervix. A strong silk ligature, carried by a laterally curved aneurism-needle, is passed from before backward, and from above downward, and about $\frac{3}{4}$ inch to the outer side of the cervix, and including about $\frac{3}{4}$ inch of broad ligament tissue. The ligature is firmly tied and the broad ligament included is immediately divided with scissors, rather nearer the uterus—being careful not to make the division higher than the ligature has gone. Two or three ligatures can generally be applied to one side before placing the same number on the opposite side, during downward traction of the uterus to the side where the first ligating was done (always drawing it to the side opposite the one upon which the greatest exposure is wished). Or the ligating may be continued on one side as far as convenient, even to the cornu of the uterus, and then upon the other side. The uterine vessels are generally included in the second or third ligature, being found close to the cervix uteri near the os internum. The position of the uterine artery should be determined as soon as the opening through the posterior fornix is made. Especial care is here taken to avoid the ureter. When the ligating and division have progressed nearly to the cornu of that side, the finger can be passed in behind and hooked over the remaining broad ligament, fallopian tube, and round ligament, and these brought down and ligated—this last ligature being tied par-

ticularly well and the tissues cut at a distance. Often it is easier to alternate—by tying two or three ligatures on one side—then on the opposite, and so on. When all of one side and nearly all of the opposite broad ligament has been tied, the finger may be introduced and hooked around the fundus of the uterus and the organ delivered sideways—the remaining ligatures being applied either from below upward or from above downward, as most convenient, while the organ lies in the vulval fissure. (5) The right and left groups of sutures are separated and held aside and the lower pelvic cavity irrigated and mopped or sponged out. Each line of broad ligament ligatures must be inspected—suspicious ones replaced—and additional ones applied where indicated. The ligatures of each side are tied together in one group and cut near the knot, closely within the vagina. (6) The cut edge of the vesico-uterine peritoneal fold in front is sutured at its middle with gut to the middle of the cut edge of the utero-rectal peritoneal fold behind—either by a single mattress suture bringing the central portions of the two peritoneal folds together, or by a continuous suture bringing together the central portions—leaving, in either case, a gap at either side for possible drainage in cases where the vaginal vault is not sutured, or only sutured in part. Where the vaginal vault is entirely sutured, the two edges of the peritoneum should be sutured together throughout. (7) The vaginal vault may be left entirely unsutured—in which cases it is packed loosely with gauze, and the vagina is then packed rather snugly. In other cases, which method is to be preferred, the vaginal vault is entirely closed by a line of continuous or interrupted gut sutures bringing the cut edges of the fornices together and crossing the dome of the vagina from before backward. But at each side the lower portion of the ligated broad ligament is caught and drawn down into the upper part of the vagina, and the sutures which pass through the lips of the vaginal vault also pass through and include some of the broad ligament stump—the stumps on the two sides thus projecting into the vagina, thus insuring drainage.” (*Bickham's Operative Surgery.*)

9. *Treatment of carbuncle:* “The most thorough and satisfactory is to lay the carbuncle freely open under an anesthetic, and scrape with a sharp spoon or cut away all sloughs until healthy tissue is reached, and then to disinfect the cavity thoroughly with pure carbolic acid or peroxide of hydrogen (10 volumes). The hollow thus formed is packed with gauze soaked in an iodoform emulsion (10 per cent.), and allowed to heal by granulation. Good food, iron, quinine, and alcohol according to judgment, must be administered, whilst appropriate medicine (e.g., codeine or opium) and limitations of diet are necessary in diabetic patients.” (*Rose and Carless' Manual of Surgery.*)

10. *Treatment of diabetic gangrene:* “In the less severe cases, limited to one of more toes, it will often suffice to keep the part warm and aseptic, until it is separated by natural processes, or at any rate the surgeon merely completes the work by dividing or dissecting out bones. Naturally, the elimination of sugar must be checked, if possible, by suitable diet and the administration of codeine. In more extensive trouble the character of the treatment turns largely on the amount of vascular disease and the degree of the accompanying inflammation. If the vessels are tolerably healthy, amputation not very much above the upper limit of the gangrene is justifiable; but if the main trunks are probably affected, a high amputation will be required, if the patient's general condition permits, although there is some risk that diabetic coma may supervene. When extensive suppuration is present, it is sometimes wise to lay the parts open for awhile and drain away the inflammatory exudations before considering the question of radical treatment. The choice of the anesthetic will also require careful consideration; and spinal analgesia should be employed when the lower extremity is involved.” (*Rose and Carless' Manual of Surgery.*)

OBSTETRICS.

1. *The cord should be tied when respiration is well established, and marked pulsation in the cord ceases, or the child cries lustily; say about ten minutes.*

The placenta is generally delivered in about fifteen to thirty minutes.

Delivery of retained placenta: “A finger—one or two—must be insinuated between the uterus and placenta at some point already partially separated, or, if no partial separation exists, at a point where the placental border is thick, and then passed to and fro, transversely, through the uteroplacental junction, acting like a sort of blunt paper knife, until separation be complete. Another mode is to find or make a margin of separation as before, and then peel up the placenta with the finger-ends, rolling the separated portion toward the palm of the hand upon the surface of the still adherent part. Great care is necessary to avoid peeling up an oblique layer of uterine muscular fiber, which might split deeper and deeper until leading the finger-ends through the uterine wall into the peritoneal cavity. Should such a splitting begin, leave it alone and recommence the separation at some other point on the placental margin. It is sometimes only possible to get the placenta away in pieces. These should be afterward put together and examined to indicate what remnants are left behind. It may be quite impracticable to get out every bit, but small remnants or thin layers too firmly adherent for removal do not distend the womb enough to create hemorrhage from their bulk, and the subsequent danger of septicemia from their decomposition may be obviated by injecting warm (2 per cent.) creolin water into the uterus twice daily, until everything has come away.” (*King's Obstetrics.*)

2. *Albuminuria* in small amounts, at irregular intervals, has been regarded as physiological on account of its frequent presence without apparent unfavorable symptoms. The anatomical basis for this has been supposed to be the so-called pregnancy kidney, which has been described as a congestion from the pressure of the altered circulation. The safer position is to assume that any amount of albumin is pathological, provided we have the assurance that it is not due to the admixture of discharges from the external genitals. Its clinical significance may be unimportant in some cases. The amount is generally small, not even appearing in some of the severest types until late in the disease. This may be true even in the later months in the form that terminates in *eclampsia*, in which it may suddenly appear as the attack begins. In such cases daily and even hourly examinations may be necessary.” (*Jewett's Obstetrics.*)

Albuminuria with no uremic manifestations: “The urine should be examined every month in the first six months of every pregnancy, no matter how normal it may seem, and every fortnight in the last three months. If albumin is present, the amount should be estimated in an Esbach tube, and the urea in a Doremus ureometer. The total quantity of urine per diem should also be ascertained. The principles of treatment are to relieve the kidneys by free elimination by the bowels and skin, and by diminishing the nitrogenous part of the dietary; and at the same time to prevent any further interference with the renal functions by guarding against cold. In mild cases where the albuminuria is the sole symptom, the patient should be warned to rest and guard against cold. The diet should be restricted to milk food, with bread and butter, and a little fish or chicken once a day, and the bowels should be made to act freely once every day. (*Johnstone's Textbook of Midwifery.*) And see below Question 4.

3. *Hemorrhages of labor:* Caused by (1) placenta previa; (2) premature separation of a normally situated placenta; (3) relaxation of the uterus; (4) laceration of cervix; (5) rupture or inversion of the uterus.

Prophylactic treatment consists in keeping the patient quiet, if necessary in bed, and conducting the labor with the utmost care.

4. *PUERPERAL ECLAMPSIA. Symptoms:* Headache, nausea, and vomiting, epigastric pain, vertigo, ringing in the ears, flashes of light or darkness, double vision, blindness, deafness, mental disturbance, defective memory, somnolence; symptoms easily explained by the circulation of toxic blood through the nerve centers. These may be preceded by lassitude, and accompanied by constipation or by diarrhea. Headache is perhaps the most significant and common warning symptom. In bad cases the urine is reduced in quantity (almost

suppressed), very dark in color, its albumin greatly increased, so that it becomes solid on boiling. Next comes the final catastrophe of convulsions. The convulsive fit begins with twitching of the facial muscles, rolling and fixation of the eyeballs, puckering of the lips, fixation of the jaws, protrusion of the tongue, etc., soon followed by violent spasms of the muscles of the trunk and limbs, including those of respiration; hence lividity of the face and stertorous breathing, biting of the tongue, opisthotonus, etc. The fit lasts fifteen or twenty seconds, ending in partial or complete coma, possibly death; or consciousness may return, to be followed by other convulsions."—(King.)

"The treatment of the attack consists of the administration of chloroform by inhalation, chloral hydrate (gr. 60) by enema, and the fluidextract of veratrum viride hypodermically (gtt. 15 followed by gtt. 5 repeated frequently enough to keep the pulse at about 60 beats a minute), to control the convulsions, and free purgation by croton oil (gtt. 2, or 3, in sweet oil or glycerin), free sweating by the hot pack, and sometimes depletion by venesection to eliminate the poison. The after treatment consists of free purgation by the salines, restriction of diet, and later the administration of tonics and stimulants. The obstetric treatment is usually noninterference."—(*Pocket Cyclo-pedia*.) Sometimes *accouchement forcé* is indicated.

5. *Diagnosis of Breech presentation.* Abdominal palpation reveals the head above, which is round, hard, and freely movable; the breech below, soft and irregular in outline. The heart-sounds are heard above the umbilicus. Vaginal examination shows a high position of the presenting part; after dilatation of the os the characteristic features of the breech may be detected—the sacrum and coccyx, the external genitalia and anus, the nates and thighs. There is usually evacuation of meconium.

The dangers to mother and child in a case of breech presentation are: (1) Compression on the umbilical cord; (2) premature respiration; (3) asphyxiation of the child; (4) the child may suffer from fractures, dislocation, hemorrhage, or paralysis; (5) extension of the head, or of the arms over the head; (6) increased tendency to rupture of the perineum.

SPECIALTIES.

1. The incubation period of syphilis is usually two to three weeks. Secondary manifestations usually appear from one to three months after the infection, or about six weeks after the chancre. Some lesions of the tertiary period: Gumma; lesions on the skin and mucous membranes; visceral lesions (in liver, kidneys, lungs, bones, heart and arteries, and nervous system).

2. Corneal ulcer is caused by an external wound leaving an opening for the entrance of a suppurative process, by intense conjunctival inflammation, or by some deep inflammatory process that leads to a destruction of the superficial layers and epithelium.

Treatment of corneal ulcer: The treatment consists in putting the eye at rest, instilling atropine, and the application of a bandage. Leeches to the temple will relieve the pain. Hot compresses have the same effect. The eye should be douched with sublimate solution, 1:5000, and iodoform dusted upon the cornea. Stronger sublimate solution, boroglycerid 50 per cent., and formalin 10 per cent. are sometimes necessary. Cauterization is occasionally indicated. If perforation seems probable, it should be hastened by a puncture.—(*Cyclopedia of Medicine and Surgery*.)

3. Inflammation of the Mastoid cells is diagnosed by: Tenderness, pain, swelling and redness over the mastoid; bulging of the superior and posterior parts of the auditory canal; temperature variable, from normal up to about 104° F.

4. Forms of nasal polypi: Simple or mucous, and fibrous or fibro-sarcomatous.

Operation for removal of mucous polypi: "In undertaking avulsion by forceps, the patient is seated in a chair, and the surgeon sits or stands in front of him. The nasal cavities are well sprayed with a solution of eucaine or cocaine (5 per cent.) and adrenalin (5 per cent.), and the situation of the pedicle ascertained by inspection and by the use of a probe. The forceps employed should be long, with delicate, though strong, blades, which are deeply serrated on either side of a

median groove. They are introduced open, with a blade placed horizontally on either side of the growth, and are gently pressed upwards until the pedicle is grasped as close to the turbinated bone as possible. The blades are then closed firmly, and the polyp twisted off and removed, a certain amount of hemorrhage resulting. The same process is repeated to the smaller tumours until the nostril is clear. It may be plugged with a strip of sterilized gauze if there is much bleeding, but such should never be left unchanged longer than twenty-four hours. The plug is then removed, and the base of the growth carefully examined and cauterized with the galvano-cautery by the aid of a nasal speculum. This cannot be so accurately accomplished immediately after removal, as the bleeding interferes with clear vision. The cauterization of the base is a most important item in the treatment, as without it the growths are sure to recur. The patient should be again examined after a short interval, so that any smaller polypi which have commenced to develop may be suitably dealt with." (Rose and Carless' *Manual of Surgery*.)

5. CHRONIC FOLLICULAR PHARYNGITIS. *Symptomatology and Diagnosis.*—"There is a sense of ever present irritation of the throat. The amount of secretion varies according to the pathological change and may be profuse, thin, viscid or scanty. Huskiness of the voice and coughing follow the prolonged use of the voice in the adult. The quality of the voice is notably impaired. The general appearance of the pharynx varies and is that of a venous engorgement, of a pale pink, resembling the normal. The follicles appear red and project above the surface, sometimes surrounded by varicosities. The tonsils may be enlarged and cryptic, containing infected cheese-like debris.

Treatment.—"The treatment is directed to the correction of any gastro-intestinal disorders, injurious habits, rest of the voice, general tonics and training in the correct use of the voice. The local treatment consists in the removal of any nasal obstructions and cryptic tonsils. The destruction of large follicles and varicosities is best done with the galvano-cautery. Care should be taken in the use of the cautery to avoid too great destruction of tissue at one time on account of the tendency to produce cicatrices which become a permanent source of irritation. Previous to the use of the cautery, the pharynx should be sprayed with a five per cent. solution of cocaine, which renders the application of the cautery painless." (Kyle's *Diseases of Ear, Nose and Throat*.)

Pyosepticemia Simulating Generalized Tuberculosis.

—Achard and Gardin relate a case in *La Médecine* for December, 1920, ii, 3, in which, after a history of tuberculous coxitis, ordinary septicopyemia developed from the joint focus. The patient when first seen was a man of twenty-five. As a child he had suffered from hip disease on the left side and had been treated by resection of the head of the femur. The cicatrix, which was in evidence, had remained quiescent. Three weeks before consultation the present affection had begun by pain in the affected hip, with temperature of 104° and pulse 120. The diagnosis was typhoid fever or acute general tuberculosis. Hemoculture, however, disclosed streptococemia without the coexistence of any other microbism. The clinical picture of sepsis appeared later, with its chills and abundant sweats and its temperature fluctuations, but for a considerable interval the patient did not look septic and the general condition in this respect was still good. There were symptoms which suggested secondary foci of sepsis, but they were abortive until an arthritis of the left knee developed. There were no further foci apparent, but the general condition became aggravated and after the development of oliguria, insomnia, anxiety, dry tongue, etc., the patient died, his temperature having become almost normal. Autopsy showed no serious anomalies of the intrathoracic organs. There had been a slight swelling in the suprahyoid region and a little pus was found here. The kidneys were only congested. There had been an abortive arthritis of one elbow and a focus in the base of the right lung had been limited to congestion and a little dry pleurisy. The total evolution of the process measured six months.

Miscellany.

NEW BOOKS AND OLD.

VI. THE FITZ-PATRICK LECTURES AND MEDICINE IN ENGLAND DURING THE REIGN OF GEORGE III.

By JOHN RICHARD, M.D.,
BALTIMORE, MD.

THE College of Physicians of London boasts a lectureship devoted to the history of medicine. The first Fitz-Patrick lecturer in 1903 was Joseph Frank Payne, Harveian librarian of the College of Physicians. His lectures were entitled "English Medicine in the Anglo Saxon Times," and of these entertaining addresses more at another time. From his introduction, however, we learn that the lectureship was established by Mrs. Fitz-Patrick in memory of her husband, Thomas Fitz-Patrick, himself a member of the college, and as Payne says, "A physician of great worth, learning, and accomplishment." The lectureship was to promote an object in which Fitz-Patrick himself was much interested, the advancement of medical history.

Dr. Fitz-Patrick was born in 1832 at Virginia, a little town at the end of Lake Cavan. He was educated first at the college in the town of Carlow, and afterwards in Trinity College, Dublin, where he was graduated M.D. After practising a short time in one of the villages not far from his birthplace, he went to India in the medical service of the East India Company. Owing to a serious illness while in the East, he repaired to London, where he practised throughout his life.

The district of Ireland in which Fitz-Patrick was born, according to Norman Moore, is the birthplace of several old Irish poets, musicians, and historians, and in the eighteenth century, the home of such writers as Henry Brook and Thomas Sheridan. Moore believes that the literary association of his early life had much to do with the influencing of the later tastes of Dr. Fitz-Patrick. He was a man of great learning, well read in the classics, a lover of Don Quixote, which he read in the Spanish text; he was also familiar with Italian, French, and German as well as some of the other languages.

The idea of a lectureship devoted to the history of medicine is said to have originated with Norman Moore, who has done so much for the study of the history of medicine in Great Britain.

Medicine in England During the Reign of George III.—In 1917-18 the Fitz-Patrick lectures were delivered by Arnold Chaplin, who took for his subject "The Development of Medicine During the Sixty Years Reign of George III." The book is one which can be recommended for the historical section of any library, and while it is not as readable as some of the other lectures, contains a vast amount of interesting material, accessible otherwise, it is true, but put together in such a way as to give a good picture of the medical profession of the times. This was the period of the systems in medicine, the Animism of Stahl, the Ether of Hoffman, the Solidism of Cullen and others. This was the period when physicians were more given to theorizing concerning disease, than they were in making clinical studies, or observations on the

post mortem table, but the work of Morgagni and others was soon to make a change for the better.

I must refer the reader to the volume in question for his entertaining account of the conditions of medical practice in London, for the medical laws and relations, and medical education. I cannot refrain from quoting, however, Chaplin's account of the medical societies of the times.

Further evidence of medical activity in this reign is found in the rise of the numerous societies devoted to the advancement of medicine. Probably the earliest society of this kind of which we have any record was one founded by Glisson about 1650, and mentioned in his work on Rickets. The next was the Society of Naval Surgeons, which began its career in 1746. This society engaged Mr. Sharp to deliver lectures on surgical operations, and met at a house in Covent Garden. Sharp was soon succeeded by William Hunter, who continued the course for several years. In 1752 a Medical Society of Physicians was founded, chiefly owing to the energy of Fothergill, and met at the Mitre Tavern. The next to be formed was the "Society of Licentiate Physicians" in 1764 by Fothergill and Alexander Russell. Licentiates of the College only were eligible for election, and the meetings were held at "Old Slaughter's Coffee House," but once a quarter the members dined at the "Crown and Anchor." In 1767, at the instigation of Dr. Heberden, the "Meetings of the College of Physicians" were begun, and between that date and 1820 six volumes of transactions were issued. 1771 saw the foundation of the "Guy's Physical Society," by Dr. William Saunders, and the same year witnessed the establishment of the Physico-Medical Society. The Medical Society was founded in 1773, and in the following year the "Middlesex Hospital Society" began its career. Mr. John Sheldon formed a Medical Society in 1779, which met at his house in Great Queen Street, and in 1762, owing to the efforts of Dr. Simmons, Dr. Fordyce, and John Hunter, the Society for the Improvement of Medical Knowledge was established, the meetings being held at "Old Slaughter's Coffee House." Fordyce was also responsible for the foundation of the "Lycæum Medicis Londinense" in 1785. Finally, the "Medical and Philosophical Society of St. Bartholomew's," renamed in 1832 the "Abernethian," was formed in 1795, the "Medico-Chirurgical" in 1805, and the "Hunterian" in 1819. A Society of Physicians to Dispensaries met in the Borough about 1780, but the exact date of its foundation is uncertain.

It will thus be seen that twelve medical societies were formed during the reign of George III, and three only before that period. Many of them came to an end after a few years of usefulness, but six remain and are flourishing at the present time. Among those who did so much to encourage the formation of these London medical societies the names of Fothergill, Simmons, Lettsom, Fordyce, and William Hunter must be forever honored. They toiled, not unsuccessfully, for the advancement of medicine, and for a wider medical polity where men holding diverse opinions could meet and exchange their views.

In the provinces also three medical societies were formed during the reign. The first one being the Colchester Medical Society in 1774. This was followed by the Plymouth Medical Society in 1794, and the Leicester Medical Society in 1800, but previous to the formation of these three societies there is no record to be found of any similar society existing in the provinces. To complete the review of the establishment of medical societies, it remains to be said that toward the end of the eighteenth century six medical benevolent societies were founded in the provinces and one in London, all of which are flourishing at the present day.

The first English medical journal was printed in 1684, but only two numbers appeared. The only other medical journal prior to George III. was *Medical Essays and Observations*, started in Edinburgh in 1737, and continued to 1757. In those days when one addressed the medical profession, or any other group of readers, for that matter, it

was done by the means of "Letters," "Observations," or "Considerations." The library of the College of Physicians contains a very large collection of such contributions. We may quote Chaplin on the subject:

In 1757 *Medical Observations and Enquiries*, promoted by a Society of Physicians, was established, and for many years enjoyed a considerable popularity. The next journal to appear was the *Medical Museum* in 1763, a volume devoted to "Select Cases and Experiments and Discoveries in Medicine and Pharmacy." The following year "Medical Essays and Observations" made its appearance, and was composed of abridged Memoirs of the Royal Academy of Sciences in Paris. After this in 1767 the "Medical Transactions" of the College of Physicians was begun, at the instigation of the elder Heberden. Six volumes of these "Transactions" were published, the last appearing in 1820. The *London Medical Journal* was founded in 1781 by Dr. Simmons, who was its first editor, and in 1791 it was continued as *Medical Facts and Observations*. Dr. Simmons was also responsible for the *Medical Communications* which began in 1784 as the journal of the "Society for Promoting Medical Knowledge," but after two volumes were issued it ceased in 1790. Three volumes of the *Medical Spectator* were published between 1791 and 1796, and two of the *New London Medical Journal* in 1792-3. In 1793 the "Society for the Improvement of Medical and Chirurgical Knowledge" issued its first volume of Transactions, and at intervals two other volumes were published, the last appearing in 1812. They were all edited by Dr. Wells. The *Medical and Chirurgical Review* began its career in 1795, and continued until 1807. In 1799 the *Medical and Physical Journal* first appeared, and survived until 1833. The *London Medical Repository* was first published in 1814, and under various titles continued to appear until 1836. Besides these periodical publications, the Transactions of the Medical Society and of the Medico-Chirurgical Society were being issued from time to time. The list is a full one, and bears striking testimony to the great activity taking place in every branch of medicine during the closing years of the eighteenth century.

It was not until 1832 that the *Lancet* appeared and quickly enjoyed a wide popularity. The cause of its success was to be found in its powerful advocacy of medical reform, which was sadly needed, and in the great ability with which it was conducted. It not only appealed to the strictly medical mind, but also to the more progressive spirits in the profession, who relished its truculent tone toward existing medical authority. Its methods were sometimes questionable, but always undeniably clever, and when such matter as the incomparable "Intercepted Letters" by Wardrop appeared, although the medical world was convulsed with laughter, the fact cannot be denied that the good taste of such journalism was doubtful.

The memoirs of many of the most celebrated physicians of the period are to be found in the Roll of the College of Physicians, which will ever be a monument to its able compiler, Dr. Munk, and in the Dictionary of National Biography, most of the sketches in this were written by Norman Moore.

As Chaplin says, a very excellent idea of what was taught in the first thirty years of George III's reign can be gained by looking over the popular text book of the period, "The Elements of the Practice of Physic." George Fordyce, the author of this popular work, is more famed for his wonderful gastronomic feats at Dolly's Coffee House than for his contributions to medicine. This was the period of Heberden, Fothergill, of the Hunters, Baillie, all of whom, and many others, are commented on in the volume in question. He also touches briefly on the achievements of Thomas Young, one of the great lights of British medicine

and science, and as some one has said, "the last man to know everything."

Chaplin also traces the changes in the care of the insane, the advent of vaccination, public health, and devotes a certain amount of attention to army and navy services.

Perhaps the most interesting part of the book is his account of the illness of the king, and the physicians who looked after him. Chaplin truly remarks:

The lot of kings when stretched upon the bed of sickness is far less enviable than that of humbler mortals. Politics and the august presence of royalty seem to conspire together to paralyze the efforts of physicians, and it may be doubted if the prognosis in cases of illness among kings can ever be regarded in so favorable a light as in those of more lowly beings.

He goes on to state that great figures in literature are able to command the ability and sympathy of the physicians who attend them, and to illustrate this point he gives an account of Samuel Johnson's last illness. This is much too long to quote, but is well worth perusal. I can, however, take up space enough to give to the last two pages of Chaplin's lecture, which need no comment.

Although the days have long since passed when the mere mention of medical history raised a smile of genial sarcasm, many of us would be glad to see a still wider interest shown in the subject. Sound arguments may be advanced in support of this desire. At the present day, the immense range covered by the word "medicine" leaves but little time for the cultivation of extraneous studies which both elevate the mind and increase its usefulness in human life and endeavor. For this reason the title of "physician" is not now so synonymous with culture as it was in former years. Indeed, with the multifarious duties which fall to the lot of physicians in these days, it is wellnigh impossible to expect of them a wide and profound acquaintance with subjects outside the sphere of their immediate and pressing work. But a study of the history of medicine would permit the physician, while still tethered to his life work, to roam in a wide circle into the realms of history, biography, philosophy, and all the activities of the human mind. It would, at least, be a hobby, and so long as a hobby does not overwhelm the main purpose in life, it implies no disgrace, but rather operates as an agent of high recuperative value.

It has been urged that a study of this subject cannot advance our knowledge of present-day medicine. That may be true. But how can knowledge of any part of medicine be complete without an investigation of the early steps taken from hypothesis to accepted fact. The Church, the law, politics, art, and science all have their histories. Why should medicine, the meeting point of all human emotions lag behind?

If medical history be deemed worthy to form part of the education of physicians, surely no more fitting place can be found for its abode than the College of Physicians, the ancestral home of physicians for four centuries. The College has founded the Fitz-Patrick Lectures for the purpose of encouraging the study of the history of medicine, and is thus the first medical body in this country to accord recognition to this particular subject. The connection between the College and medical history is of the most intimate nature, and it is impossible for those belonging to it to remain uninfluenced by its great traditions. There everything around reminds them of the history of British medicine. On the staircase, in the reading room, and in the Censors' room they gaze on the portraits of physicians who have labored to advance the knowledge of medicine. The choice and magnificent library contains rich stores contributed by the great master-builders of the past. At the College meetings the Fellows occupy seats once filled by their great predecessors, Heberden, Baillie, Arbuthnot, Freind, Young, and Bright. The Presidential Chair recalls to them the long line of distinguished physicians who have adorned that emi-

nent position, down to the present occupant, who has done so much to encourage learning and the study of the history of medicine. It is a great heritage, and in proof of its vitality, it need only be stated that, while dynasties and empires have risen and crumbled in decay, the Royal College of Physicians is still, after four centuries, at the full tide of its strength and influence.

We cannot afford to neglect the study of this branch of medicine. Veneration for those who have labored to perfect the knowledge of our art, and the desire to be exactly informed concerning their work make it incumbent upon us to include this subject among those required for a complete medical education.

The Doctor.—The alleged rapacity of doctors is one of the meanest of libels. It is contradicted by common knowledge and every-day experience. The physician who thinks first of his fee is a rarity. The young woman of Trenton who was ready to sell herself in marriage for \$1,000 to pay for an operation on her mother need only have gone to the nearest hospital and not a cent would have been asked. A Brooklyn doctor a few days ago got up from a sickbed to take a bullet from the brain of an insane prisoner. His fee was—nothing.

From the time of Galen the medical profession has been the butt of the jesters. Most of the jokes are variants of "The surgeon buries his mistakes." Addison, in *The Spectator*, thought it good humor to write: "We may lay it down as a maxim that when a nation abounds in physicians it grows thin of people. . . . This body of men in our own country may be described like the British army in Cæsar's time. Some of them slay in chariots and some on foot. If the infantry do less execution than the charioteers it is because they cannot be carried so soon into all quarters of the town and dispatch so much business in so short a time." Yet there were doubtless fifty doctors in London who would have given their days and nights to Addison, though he hadn't a guinea to pay.

It is only in modern letters that we find real appreciation of one of the noblest of professions—in the poems, for example, of William Ernest Henley, who knew what it meant to be In Hospital. It is good to feel that these lines from his sonnet "The Chief" truly express a sentiment that is general to-day:

If envy scout, if ignorance deny
His faultless patience, his unyielding will,
Beautiful gentleness and splendid skill,
Innumerable gratuities reply.

Doctors are no doubt lower than the angels, but in whose daily labor is there more of unselfish service to fellow human beings?—*New York Tribune*.

Pneumonic Plague in Vladivostok.—A serious outbreak of pneumonia plague has occurred in Vladivostok, according to a cablegram received at the National Headquarters of the American Red Cross in Washington, from its representative there, D. O. Lively, of San Francisco. Pneumonic plague appeared once before in the Far East in the winter of 1910-11 when it exacted an enormous toll of lives before an international commission of medical experts found a means of checking it. Appearing without warning in Manchuria this pestilence not only killed thousands of natives with

almost unbelievable speed but caused grave concern to the rest of the world.

Unable to cope with the situation at that time, the Chinese government appealed to the nations of the world. The United States government turned to the American Red Cross which commissioned Dr. Richard Pearson Strong, who at that time was studying tropical diseases in the Philippines, to proceed to the stricken area. Dr. Strong was accompanied by his assistant, Dr. Oscar Teague, and they spent five weeks studying the plague at first hand before the international commission of medical experts met at Mukden to begin an organized fight against the disease.

The measures proposed by the international commission were put into effect, with the support of the Chinese government and the scourge, which had threatened to spread all over China, to the Pacific Islands, and possibly to this country, was finally suppressed. It was not overcome, however, before 65,000 natives and several of the foreign doctors and nurses had succumbed. The report of the international commission traced the outbreak to the Russian tarbagan or marmot, which had long been known to be the victim of a mysterious malady and from which some Manchurian hunters were found to have contracted the plague.

A Thirty-seven Day Therapeutic and Ambulatory Fast.—According to Babonneix in the *Gazette des Hôpitaux*, one Dr. Maglionni happened some time ago to read of the hunger treatment of disease, and was the more interested because he chanced at the time to be suffering from duodenal ulcer. A surgeon himself, he would on no account submit to gastroenterostomy and began to practise short fasts followed by longer ones. He first went only two or three days and then jumped at once to a fast of 19 days. Having learned the art of therapeutic fasting he went to London to undertake a prolonged experiment. This was begun June 20, 1915. Evidently his ulcer had benefited as a result of his earlier fasts. He for some reason found his London fast very different and was with difficulty able to deny himself at the outset. He took but little water and slept well, but on waking there was at first the obsession to eat. He had a special longing for dishes which he had liked as a young child—such as boiled sheep's head, tongue, and brains. He tried partaking of mental meals. He had formerly amused himself in this way, reading the menus posted at the entrance of public restaurants and eating in imagination the various courses. He would weigh himself on the public scales and note his weekly losses. He conducted his fast in a lodging house and came and went like any inmate, so that his landlady knew nothing of what was going on. He was, in fact, away all day, stating that he went to the clinics and ate in restaurants. Startling to relate he pursued this course for 25 days before he became too weak to climb stairs. On the 37th day he capitulated. He had no unusual appetite when he broke his fast. The sheep's head dish had ceased to tempt him and anyway he could not find one in London. He began on rice, beans, potatoes, apples, and oatmeal. He seems to have been the one faster who did not fast for exhibition or political purposes.

GASTRIC ULCER AND ITS TREATMENT.*

By SIR J. BERKELEY MOYNIHAN,
LEEDS, ENGLAND.

WHEN the subject of "Gastric Ulcer and Its Treatment" is announced in connection with so important an event as the "Wesley M. Carpenter Lecture" I can well believe that many physicians and surgeons will wonder if any new matter, or any revision of old matter can justify the orator in his choice. Yet I am quite unabashed. I believe that error has crept in upon the subject to a degree which is even now quite inadequately recognized; that for many of the statements which readily find acceptance, and that for much of the treatment to which patients are still submitted there is no real foundation in adequate knowledge. For every one must agree that unless the diagnosis of Gastric Ulcer is accurately made, any kind of medical or surgical treatment based upon it is irrelevant and wasteful, and any conclusion drawn therefrom necessarily false.

The literature of the subject is illimitable; it is in medicine as in finance, much paper and much poverty may coexist. Much dross has been foisted upon us as pure gold, and we have meekly accepted it as such because of the high authority or the specious phrases of the writer

As on the finger of a thronéd Queen
The basest jewel will be well esteemed,
So are those errors that in them are seen
To truths translated and for true things deem'd

All that has been written requires I think the most ruthless scrutiny in the light of the new truths disclosed by the work of the surgeon and of the radiographer. Heartless as it may appear, I venture, with diffidence but with hope, to suggest that a complete reconsideration of this subject by physicians may be undertaken. It is I think true to say that any one who has been engaged in a study of the subject will agree that gastric ulcer has been regarded as a disease of frequent occurrence, and of easy diagnosis, with the application of the ordinary methods of clinical inquiries. By degrees, however, it has become incontestable that the disease is uncommon, less frequent than duodenal ulcer, that it is closely mimicked by several other disorders, and that consequently its recognition, even after the most meticulous care has been exercised in the review of all the clinical facts, is by no means easy or

certain. If my own experience can be taken to have a representative value it is true to say that in more than half the number of cases in which the diagnosis is made in every day practice, and by the ordinary methods, it is inaccurate.

In the early days of our consideration of this subject we did not discriminate with accuracy between a gastric ulcer and a duodenal ulcer, and even today the differentiation is not understood as it ought to be. In recent Swiss and French literature the frequency of "pyloric" and "juxtapyloric" ulcers makes the total number of gastric ulcers larger than the number of duodenal ulcers, and a French surgeon possessed of one of the most acute intellects of the day has recently written, "Ulcer of the lesser curvature of the stomach is a special type of Cruveilhier's disease as clear as is pyloric ulcer," and I have seen in France and elsewhere, ulcers spoken of as "pyloric" and "gastric" which quite unmistakably lay in the duodenum. There is no excuse for these errors, for errors they certainly are. The stomach is marked off from the duodenum by the pyloric vein and the pyloric white line so distinctly, that the possibility of a mistake is certainly less than 10 per cent. Any one who cares to examine the points which I have previously described in detail, or who will make sections of the pylorus for examination by the microscope, will be satisfied as to the accuracy of these statements. Ulcers occurring no near to this boundary line as to be entitled to the term "pyloric" form almost exactly 1 per cent. of the total number of ulcers in the stomach or duodenum. Ulcers on the proximal side of the boundary are "gastric," on the distal side "duodenal." In the last 10 years I have operated upon 5 duodenal ulcers for every 2 gastric ulcers. Before that time the proportion of duodenal ulcers was even larger.

The symptoms of gastric ulcer are said by all authorities to be pain, vomiting, and hematemesis. Now these symptoms alone, or any combination of them are common enough; if their presence in any case is taken, as it so commonly is taken, as a warrant for a diagnosis of gastric ulcer, we can realize how it came about that the disease was considered to be of so frequent occurrence. Nothing but the closest analysis and the most anxious scrutiny of each of these symptoms individually, and of their grouping in any case, will sanction even the suspicion of the evidence of an ulcer, and before that suspicion can be confirmed, other methods of investigation must also be employed. What, then, are the characteristics of these several symptoms?

Ulcer of the stomach occurs twice as often in men as in women; its chief symptom is pain. All

*The Wesley M. Carpenter Lecture at the New York Academy of Medicine, October 21, 1920.

the attributes of this symptom merit and must receive the closest scrutiny. The chief attribute is, I think, regularity. In all cases of gastric ulcer there are periods of intermission, longer or shorter, at one period of the year or another; but when the attacks are present the pain, which is then the chief complaint, always displays regularity. It comes after all meals, even light meals; it is not present after breakfast on one day, after dinner on another, and absent entirely on another day. If during the attack a meal is eaten, pain follows invariably. The interval between the taking of the meal and the onset of pain is fairly constant. As a rule the earlier the pain is felt after a meal the nearer is the ulcer to the esophagus. That is to say, if pain comes, regularly, one hour or one hour and a half, the ulcer that causes it is in the stomach, it is a "prepyloric" ulcer. If the pain comes two, three, or four hours after a meal the ulcer lies generally beyond the pylorus. This period of relief from pain after a meal is constant and invariable, both in gastric and duodenal ulcers, until stenosis, subacute perforation, or the formation of crippling and embarrassing adhesions takes place. These conditions may lead to a delay in the time of the appearance of the pain in cases of gastric ulcer, or to the hurried appearance of the pain in cases of duodenal ulcer.

In over three cases in five of gastric ulcer, seen during operation, the pain came within one and a half hours of the taking of food; in rather more than four cases in five of duodenal ulcer the pain appeared two hours or more after food. In some cases of gastric ulcer the history was considered quite typical of duodenal ulcer. In most of these the pancreas was eroded. The pain in cases of gastric ulcer very often disappears after an hour, or even less, and may be completely relieved, indeed it generally is, before the next meal is due. The pain of duodenal ulcer, on the other hand, appearing later, generally persists, often with a slowly increasing severity, until the meal is taken. The character of the meal influences the pain. A generous meal of heavy foods causes severe pain to appear at an earlier time in gastric ulcer; it delays the appearance of the pain in cases of duodenal ulcer. Smaller meals of soft, pulaceous food, easy of digestion and easily propelled, produce less pain, and the interval of relief brought by the food is longer. An indiscreet and hasty meal, especially of fruits, or salads, or pastry, may give instant and grievous pain. A bland and blameless diet taken in small quantities at brief intervals may reduce the chances of pain appearing or even afford complete relief. In a small proportion of cases pain may not be influenced by food in the manner and to the extent now described. When the ulcer is near the cardia there may be no relief from taking food, or pain may immediately be made worse; each of these features is present in approximately 4 per cent. of the cases.

The pain is variously described: it is a deep, "boring," "burning," or "aching" pain; there may be "gnawing" or a sense of "acidity" and a desire for food or warmth. The pain in a majority of cases is said to be on the left side or high in the epigastrium; in some severe types there may be great complaint of pain in the back. In twenty-three cases in which there was a deep excavation in

the pancreas consecutive to a subacute perforation of the ulcer on the lesser curvature or posterior wall of the stomach, seventeen patients complained bitterly of the intolerable aching in the back. As we know, many patients attacked with acute pancreatitis suffer most from pain in the back, and it is an old observation and an accurate one that a deep eroding ulcer of the pancreas may also produce this most distressing symptom.

The position of the ulcer, its freedom from adhesion to neighboring parts, and its size, all seem to affect the type of pain, its period of latency, and its time of onset after meals. When ulcers are small and seated high upon the lesser curvature, or just on the posterior surface, the symptoms are shorter in duration, but more prone to recurrence. They are often, as we learn from the radiographic examination, attended by severe forms of local spasm, which are responsible for the sensations of distention, weight and pressure, which appear to accompany these ulcers more often than those of other types. If the ulcer is large, excavating the liver, or burrowing deeply into the pancreas, or if it is fixed by firm, broad adhesions to the abdominal wall of the liver, the symptoms are less likely to show those intermissions which are so characteristic of the earlier stages. If, therefore, in the history of an individual case we learn that the periods of freedom from suffering have become by degrees shorter, and have finally vanished, we may often predict that some of the conditions named are present. If, in addition, there are wasting and especially anemia, we may be very suspicious of the onset of malignant disease.

About one-fifth of the patients who are found to have gastric ulcers complain not only of pain, but of great prostration, feebleness, or lassitude coming on just at the time when the pain is due. On close inquiry this most distressing symptom may be found to have preceded the experience of pain by weeks or months. The periodicity of the two is identical.

It is not possible to emphasize unduly the importance of ascertaining all these various modifications of the one symptom, pain. The constancy of the sequence—food, comfort, pain, comfort; food, comfort, pain, comfort—is the most important of all the clinical matters concerned with the diagnosis of gastric ulcer. In duodenal ulcer the rhythm is food, comfort, pain; food, comfort, pain, and so on.

The next symptom in point of frequency is *vomiting*. In all forms of ulceration of the stomach or duodenum vomiting is an inconspicuous feature, unless obstruction has developed as the result of the cicatrization of the ulcer. Indeed a degree of obstruction which is by no means trivial may be present, and yet vomiting be very infrequent or entirely absent. It is no uncommon experience to hear a patient say, "I never vomit," and for an operation to disclose an extensive ulcer or a moderate degree of stenosis in the body or near the pyloric orifice of the stomach. Patients seem to have a great capacity for estimating the degree of tolerance possessed by the stomach, and of taking only such foods, or foods in such measure as will arouse no resentment. In the earlier stages of the development of their malady vomiting is not seldom self-induced in order to ease the stomach of a heavy load and a sense of

pressure and distention. But a very little experience seems to teach the greater number of patients the quantity of food that is appropriate for them. Thereafter vomiting occurs quite infrequently. It has probably been present on a few occasions in more than half the number of patients who have suffered in many attacks; but it is rare to find that quick reference is made to it when the history is being disclosed.

When in the record of any patient suffering from "dyspepsia" there is a story of frequent vomiting of the foods, or even fluid nourishment sparsely taken at once rejected, the thought that gastric ulcer is the cause should be driven from one's mind. The type of history, which is commonly heard, is, I find, rarely present in cases of organic disease of the stomach. The vomiting due to the presence of an ulcer is infrequent, and occurs almost always not immediately after food, but after a shorter or longer interval. The meal at first causes relief, and only after that period of relief does it cause disturbance.

Hematemesis also occurs far less commonly than is supposed. Hemorrhage manifest as melena, or in the vomit, is recorded in less than 25 per cent. of my cases; in the majority of these the amount of blood lost was trivial, and of many in which "hematemesis" is recorded it is at least doubtful whether blood was, in truth, present. I think it is true to say that when blood is discharged from the stomach either in a fresh state or as "black vomit," it is commonly believed that a chronic ulcer is present. There is a great fallacy in such opinions. That gastric hemorrhage occurs, and occurs profusely, in ulceration both of the stomach and duodenum, is certain; but the number of other conditions that give rise to hemorrhage is so large that the possibility of a gastric ulcer being the source of the blood should not be strongly or exclusively held. I have so often seen hemorrhage of the most abundant kind described as "gastric ulcer," which was caused by such other conditions as splenic anemia, cirrhosis of the liver, appendicitis, and other infective conditions within the abdomen, that in the elucidation of the cause of such a condition as profuse hematemesis I seem to turn to other possibilities than gastric ulcer in the first instance. It is true that there may be a confusion as to terms here. For when a patient dies of such hemorrhage a very close examination of the gastric mucosa may reveal the existence of tiny chaps, or cracks, or fissures from which blood has certainly issued. And when in the old days of unwisdom we operated upon such patients and explored the cavity of the stomach the mucous membrane was said to "weep blood," little trickles of blood could be seen to issue from many points. But these little gaps in the mucosa are not ulcers of the kind that produce symptoms. If a patient has suffered for months or years from dyspepsia, and then is seized with an acute attack of vomiting and hematemesis, and if an operation urgently performed reveals the condition of the mucosa I have just described, it is the worst of fallacies to connect the dyspepsia with the "ulcer" or ulcers then supposed to be present in the stomach. The ulcer which has caused repeated attacks of indigestion is always a gross lesion, a lesion in which there are present not only the evidences of destruction, but also of defense; around the crater of the ulcer is an area,

greater or less, of inflammatory action, and the serous coat of the stomach is plainly involved. If the breaches of continuity which permit the escape of blood in cases of cirrhosis of the liver, splenic anemia, and the toxic conditions which, as a rule, have their origin within the abdomen are called "acute ulcers," as they often are, it is essential to remember that such ulcers are recognizable by no other clinical evidence than hemorrhage, or in exceedingly rare instances by perforation; they are never the cause of a continuing or recent dyspepsia.

The radiographic method is, in expert hands, the one certain method of diagnosis, and is now an indispensable addition to the older and far less accurate methods of inquiry.

Of the chemical examination of the stomach contents I do not speak with any enthusiasm. For several years my patients were submitted to this form of investigation, but I cannot think that the evidence thereby obtained enabled a greater accuracy to attach to the diagnosis or justified the increased trouble it gave to them. Hyperchlorhydria is present in so many other diseases than gastric or duodenal ulcer that its presence does not offer positive or even contributory evidence of any real value. In rather over 40 per cent. of the total number of cases in which an ulcer is present there is no hyperchlorhydria, and in a small number, estimated at from 10 to 20 per cent., there is a reduction in the gastric acidity. I have not yet sufficient experience to speak with authority about the newer methods of Rehfuess and others, but it is already certain that they give us far more accurate information than the earlier procedures.

Physical examination, in the absence of obstruction in the body, or at the outlet of the stomach, reveals very little. There is a record of tenderness in the epigastrium in almost every one of the patients who are subsequently found to have an ulcer in the stomach. In ulcers of the lesser curvature I have sometimes found great tenderness high up on the left, along the costal margin—tenderness which becomes more acute when the patient breathes deeply. The kind of sensitiveness is then present on the left side which on the right establishes "Murphy's sign." When an ulcer crater is seen on x-ray examination it is almost always possible to elicit pain by direct pressure over the affected areas. The signs in pyloric obstruction and in hour-glass stomach are, of course, well known.

It must now be generally recognized that many of the diseases arising in connection with the abdominal viscera are, for months or years, looked upon as cases of gastric disorder. I pointed this out a few years ago in two papers published in the *British Medical Journal* (October 18, 1907, "Pathology of the Living," and November 28, 1908, "Inaugural Symptoms"). Up to the time of the publication of these articles it had not been generally recognized that in cholelithiasis, for example, all the prodromal symptoms were attributed to defects in the stomach, and the medicaments administered were in consequence those used in gastric diseases. The same statement holds good with regard to chronic disease in the appendix, in the small or in the large intestine. We are now familiar, as the result of x-ray examination and of the chemical examination of the gastric contents, with the truth

that all these conditions express themselves in terms of gastric disturbance, of irregular hypersecretion, and of spasm. And at the time when operations are performed we can discover by inspection of the stomach such conditions as enable one to predict that a lesion will be found on closer manual examination, not in the stomach, but in the appendix or its neighborhood.

If, for example, a patient has had a type of dyspepsia which has led to a diagnosis of gastric ulcer and an operation is performed, the stomach may show no scar, nor can any examination, however careful, display the ulcer whose presence was predicted. If, however, the stomach is closely inspected before it is handled, the following conditions may be seen: the pyloric part of the stomach is decidedly redder than natural—there is a "pyloric blush." That part of the stomach is soon observed to contract eagerly and vigorously; sometimes the spasm is so severe and so prolonged that there may be a suspicion of a tumor, but by degrees the spasm relaxes and the parts become supple again. The spasm may be irregular, now at one part, now at another; now slow and deliberate, now fugitive. Along the greater curvature the glands are enlarged. When these three conditions are seen the prophecy may be confidently made that the stomach is healthy and that the appendix (or one of its neighbors in the alimentary canal) is diseased. In such cases gastro-enterostomy has often been performed, sometimes, it is curious to note, with benefit, but as a rule with disastrous effects. It has been my lot to perform a secondary operation upon many such patients, and to remove a badly diseased appendix or to resect a tuberculous intestine, and perhaps to undo the anastomosis which should never have been made. The work of Cole, Barclay, Carman, and others explains quite clearly how it comes about that these intestinal disorders affect the stomach and cause its musculature to contract in the irregular and painful manner which raises the suspicion or seems to make certain the opinion that an ulcer is present. But there is also the infective element in such cases, as Wilkie has shown experimentally, and it is the toxemia which is its outcome that leads, as Spencer and Hutchison have noticed, to profuse hemorrhages from the stomach.

The stomach is an organ full of sympathy for other sufferers. Hardly any of the viscera connected with the intestine, or the bowel itself, can be affected without the stomach playing its part in the disturbance also. This it does by pouring out an excess of secretion and by tumultuous and irregular activities. It speaks so loudly that its voice only is heard. Its tears of sympathy are spoken of as hyperchlorhydria.

The whole subject now briefly mentioned requires close and prolonged investigation. We must seek to find out as accurately as possible the clinical indication that will lead us to diagnose a veritable lesion of the stomach in certain cases, and in others to be able confidently to say that the stomach is intact, and that other organs are telling the story of their own disease in terms of stomach discomfort.

Differential Diagnosis.—The very great difficulties in the diagnosis of gastric ulcer are due to reasons which we can now fully appreciate. An ulcer of the stomach does not arouse symptoms

merely because of the gap in one or more of the several layers of the stomach. We may be certain of this because, after an "attack" of gastric ulcer is over, and the patient is wholly free from symptoms, an operation may disclose the open crater of an ulcer large or small. The exact cause of the symptoms is uncertain, but, so far as we know at present, other conditions, in addition to the structural defect, must be present before the symptoms appear. These are:

1. Evidences of infection around the ulcer, such as induration, local peritonitis, the deposit of fat in and around the base of the ulcer, and enlargement of neighboring glands. The "sentinel gland" of Lund is constant in cases of active ulceration.

2. Spasm of the musculature of the stomach. Of the presence, severity, and duration of this condition we had very little knowledge until the methods of examination by x-ray became perfected, chiefly by R. D. Carman. We now know that a high degree of spasm is present and constant in examples of ulcer of the stomach, and present, though inconstant and variable, in those cases where there is no primary lesion in the stomach.

3. An increase in the acidity of the gastric juice. This hyperacidity is by no means constant either in gastric or in duodenal ulcer, but it is possibly a factor of importance in the awakening of symptoms.

These three conditions—infection, localized spasm of the gastric muscle, and intermittent hyperacidity—are all present not only in true ulcer of the stomach, but also in varying degrees, in most of those distant conditions which are able to arouse a gastric reflex; and it is their presence which causes that mimicry of the symptoms of gastric ulcer by other lesions which may be so exact as to deceive the most expert inquirer. My own strong feeling is that in order to obtain precision where so much has been vague, no diagnosis of chronic ulcer should now be confidently accepted unless the ulcer is diagnosed by x-ray examination or is displayed upon the operation table. A fresh start in the whole matter must really be made. We can no longer accept a diagnosis of "gastric ulcer" which is based only upon clinical and chemical inquiries. We must have the additional evidence which skilled radiography now places at our disposal. The results of medical treatment cannot be estimated at their just value unless we know, with fullest accuracy, that the patients treated were in truth suffering from an ulcer in the stomach. This is a matter for the physician to settle. Will not some physician bring forward evidence that all may accept? We ask for a series of cases in which the physician, the surgeon, the radiographer are agreed that a gastric ulcer is present, in which medical treatment has been tried, in which all are confident that a healing of the ulcer has taken place, and that the healed ulcer has not again broken down. The truth as to the value of medical treatment is not revealed by the assertion that cases diagnosed as "gastric ulcer" remain well for short periods after one or other of the several methods of "cure" which bear the name of their creators. Unless evidence can be produced to show that the real chronic gastric ulcer, not the phantasm which wrongly bears the name, can be healed by medical treatment, the surgeon, who in the diagnosis of the condition walks by sight and not by faith, is

entitled to claim that his methods alone can secure the end desired. At present I do not know of any such evidence that I can accept.

SURGICAL TREATMENT OF GASTRIC ULCER.

When the diagnosis of chronic gastric ulcer is made and confirmed, the treatment of the condition may be either medical or surgical. Of the former, it is not my province to speak, but I may be permitted the reflection that as customarily carried out it cannot possibly be of real value. In England certainly, and probably in every country, the hospital accommodation is not available for the prolonged treatment of such a large group of medical cases. When a chronic gastric ulcer, the cause of recurring attacks, is seen at the time of operation, it is perfectly obvious that the healing of a condition when such gross anatomical changes are present can only be brought about by long-continued and rigid treatment. If we are to have accurate knowledge of the efficacy of such methods we must see that they are controlled from time to time by a radiographic examination. In past times, even in present times, there is too much make-believe. Of many cases we do not know that an ulcer is present, of many we know nothing as to the progress or as to the completion of healing. The result is that no evidence has yet been furnished by any physician, so far as I know, of the value of the medical treatment that he has adopted. If once the early recognition of gastric ulcer is made a matter not of surmise but of certainty, as it can surely be, and if then the most exacting and scrupulous medical methods are adopted to secure healing, and if also the radiological evidence supports the views of the physician responsible for the conduct of the cases, then, and only then, shall we be placed in possession of the truth as to the several matters I have mentioned. When medical treatment can attain these possibilities it is certain that the surgical treatment of the disease will less frequently be needed, and when needed will not be of the drastic kind that is now so often required.

The surgical treatment of a chronic gastric ulcer may call for the performance of any of the following operations:

1. Gastroenterostomy.
2. Excision.
3. Gastroenterostomy combined with (a) Excision, (b) Cauterization (Balfour),
4. Gastroenterostomy combined with jejunostomy (Moynihan).
5. Median resection of the stomach: "sleeve resection."
6. Partial gastrectomy.

1. The operation of gastroenterostomy has been the most frequently performed of all operations. In the earliest days most of the cases coming to the surgeon for relief were those in which pyloric obstruction was present. The results of the short circuiting operation were very striking and immediate and the mortality was low. Largely owing to the advocacy of Doyen the range of the operation was extended, and cases of gastric ulcer in which the lesion was in the body of the stomach, or even at the cardiac end, were treated by this operation. The results were by no means so good; there were still satisfactory recoveries, but there were many that

gave dissatisfaction. A revision of my own early cases showed that the results could be classified into three groups:

a. The Results Were Excellent.—With the same alacrity that is witnessed in cases of duodenal ulcer, or in cases of pyloric stenosis, the patient lost all discomforts, and made a speedy and excellent return to health. I had not then in all cases indicated in a diagram made immediately after the operation as I do now, the exact position and the approximate size of the ulcer; and therefore I am not able to say exactly what the condition of the stomach was in this group of cases. But in many cases it is certain that the ulcer was near to the pylorus; and that the gastroenterostomy opening was on the proximal side of it. In others the ulcer was on the lesser curvature and was small, and free from adhesions. It had not, that is to so, perforated the coats of the stomach to become adherent to the abdominal wall, liver, or pancreas.

b. The Results Were Indifferent.—Some patients were found to have improved, in many cases for periods of months or years, others were known to have relapsed. At a subsequent operation the ulcer was found to be still present; it was then removed by local excision by the cautery, or by the performance of the operation of partial gastrectomy.

c. The Results Were Bad.—In this class of cases malignant disease developed in the base of the ulcer, and so near to the ulcer as to make differentiation impossible. It was of course possible in such cases that the disease had been malignant from the first and had been unrecognized as such by the surgeon. But the lapse of time in many of them was such that even when all allowance was made for the occasional chronicity of malignant disease of the stomach there could be no reasonable doubt that the cancerous change had taken place in an ulcer that at first was simple.

The evidence as to the value of gastroenterostomy in my own cases and the conflicting views of many surgeons of equal experience led to a consideration of the means by which the operation produced its results. Two views were held:

1. That the operation was purely mechanical in its effects. The making of an opening between the stomach and the portion of the intestines created an alternative and easier route for the passage of food. Retention, therefore, did not occur; indeed, the emptying of the stomach proceeded more rapidly than normal. Now retention in the stomach is due to many causes connected with a chronic ulcer. Some of these are: (a) Cicatricial stenosis. (b) Spasm at the level of the ulcer, as shown by the "incisura" of the radiographers. (c) A spasm of the pylorus not constant but occasional, occurring even when the ulcer was in the body of the stomach or at any part of the lesser curvature. Gastroenterostomy attained its greatest efficiency when a scar at or near the pylorus was causing a high degree of obstruction. The fact that an obstructive spasm is present even when the ulcer itself does not obstruct accounts, I think, for the relief which gastroenterostomy gives in such conditions. Radiography shows that a pyloric spasm is present in about one-third of the cases of gastric ulcer on the lesser curvature. This is roughly the proportion of cases improved by gastroenterostomy.

2. The second view was that the operation possessed a "physiological" value. On this hypothesis the entrance of the alkaline bile and pancreatic juice through the anastomotic opening produces in the stomach a medium whose reaction is favorable to the healing of an ulcer. Now a cell of the gastric mucous membrane is born in an acid medium, lives its life and performs its due functions in an acid

medium, and perishes in an acid medium. If the conversion of this medium from an acid to an alkaline one is to be described in a word, it should surely be "anti-physiological." Is there any reasonable proof that an alkaline medium favors the healing of an ulcer? Of surmise there is no end. Among the methods of treatment by medical means that of Sippy of Chicago is probably as good as any. It relies, or is supposed to rely, for its efficiency upon the neutralization of the acid gastric juice by the frequent administration of alkalis. But there are many other phases in the treatment, including lavage of the stomach. The cure of an ulcer, assuming an ulcer to be present (it is an assumption rather than a certainty unless the radiologist has confirmed the diagnosis) and to be healed by the method, may be due to one or other of the constituent parts of the procedure or to the special union of them advocated by Sippy. We cannot be sure. And it is at least conjectural as to what influence the neutralization of gastric acidity may possess. The fact, too, should be remembered that a notable proportion of the cases of gastric ulcer proved to exist by operation are accompanied not by increase but by a diminution in the amount of free HCl. I cannot be brought to believe that the "physiological" action of the operation of gastroenterostomy can be supported by any argument or any experience that will bear discussion.

The following conclusions may be drawn:

(a) The results, even when the operation was "successful," were not so satisfactory as those which now follow gastrectomy. The morbidity was greater, the return to health slower, the ability to take food early and generously was wanting, a more watchful after-care was necessary.

(b) Some cases returned with the ulcer still open and a further operation was required. In such cases the ulcer had almost always perforated all the walls of the stomach, and adhesions had occurred to the liver, pancreas, or abdominal wall.

(c) Some few cases returned with carcinoma of the stomach after so long an interval as to make it probable that the cancerous change had occurred after the operation had been performed. Estimates of this sort are, I admit, fallacious, for the chronicity of some forms of malignant disease of the stomach is remarkable. I have recently been consulted, on account of a return of her symptoms, by a patient upon whom four years and seven months ago I performed gastroenterostomy for carcinoma of the lesser curvature of the stomach, causing obstruction, when secondary deposits were present in many glands, in the falciform ligament (one of these nodules was removed for microscopical examination and confirmed the diagnosis) and the liver.

It is interesting further to note that when gastroenterostomy has been performed for duodenal ulcer a gastric ulcer may develop. Sherren and I have both observed this and cases are reported from the Mayo Clinic. And Sherren records also the development in such a case of gastric carcinoma. For all these reasons I think that gastroenterostomy should be reserved for those cases in which the ulcer is distal to the opening to be made, in which no reasonable doubt can be entertained as to the benignity of the ulcer, and in which the patient's condition renders a more extensive operation too hazardous.

2. *Excision*.—The operation of excision was introduced with great hopes, which unhappily have not been gratified. I have practised excision by several routes and have removed ulcers of various sizes.

A small ulcer on the anterior or posterior surface has been excised, and the opening left in the stomach either closed by interrupted sutures of catgut or utilized to form an anastomosis with the jejunum. Wedge-shaped excision of ulcers on the lesser curvature has been carried out, sometimes with ease, oftener with difficulty, and with a resulting deformity of the stomach. Ulcers on the posterior wall, perhaps burrowing into the pancreas, have also been removed through an incision in the anterior wall of the stomach. I have been profoundly disappointed with the results. My colleague, Mr. Collinson, in a paper read before the American Medical Association in 1914, found that in thirty-nine cases of excision there were fifteen in which severe recurrence of symptoms was observed. Eleven patients were submitted to a second operation, and seven of them showed active ulceration at the site of the excision, one had developed a fresh ulcer distal to the original one, and three had extensive adhesions which crippled the action of the stomach. The operation may fail on account of technical errors. Too small an area of induration surrounding the actual crater may be removed; the hard, stiffened edges of the wound which remain, infiltrated by inflammatory products which have long been there, may not heal kindly or rapidly, and fresh ulceration may start before cicatrization is complete. Of such a condition I found evidence in a case of my own, related by Mr. Collinson, in the paper to which I have referred. In other cases a deformity of the stomach may be consequent upon the removal of an ulcer, especially of one which lay upon or near the lesser curvature; the normal peristaltic movements will then be checked at the line of suture, as a radiological examination will plainly declare. The use of unabsorbable sutures, especially continuous sutures, may lead, as shown by C. H. Mayo, to secondary ulceration. All continuous "seromuscular" sutures probably penetrate to the mucosa in more places than one; if this occurs, the suture will eventually ulcerate its way through to the lumen of the bowel and be discharged, or hang loose at the suture line for months or years. Finally, even with a careful technique, adhesions may form between the suture line and any viscus or the abdominal wall in contact with it, and some embarrassment of the action of the stomach will then certainly result.

For these reasons, and in spite of some very satisfactory results, I have abandoned the operation altogether in cases of gastric ulcer. The disappointments it brings are too many and are neither easy to foresee nor certainly to be prevented.

3. *Gastroenterostomy combined with (a) Excision, (b) Cauterization* (Balfour).—Early in our experience with excision it was found that so much deformity of the stomach might be produced by the suture or by subsequent healing along the suture line that a short-circuiting operation became necessary. A combination of excision with the anastomosis then became the rule.

Balfour, of the Mayo Clinic, to whom we owe much in connection with gastric surgery, simplified this method and improved it considerably. Instead of removing the ulcer he destroyed it by cautery. The advantages of this were many: there was adequate destruction of the ulcerated area, and in addition an effect produced in all the area around the

ulcer of such a kind as would, by the selective action of heat, destroy any tissue undergoing an early malignant change; there was less sacrifice of normal tissues; there was no difficult suturing to be undertaken; as was not seldom the case after excision, when the wound reached around the lesser curvature on to the posterior surface. The operation was shortened and made safer.

The method has proved itself one of the best ever devised in the treatment of this disease. In my own practice it has not been widely used, because at the time when it was first introduced I was being gradually persuaded by my own experience to adopt the more radical method of gastrectomy. It is, however, a most valuable measure to have at one's disposal.

4. *Gastroenterostomy Combined with Jejunostomy.*—This is a method which I have advocated and practised in cases of grave difficulty. The results have been excellent. There are ulcers of the stomach so large, so awkwardly placed, and so deeply penetrating the liver or the pancreas, in patients whose general condition is so poor that any operation becomes serious. Such cases may be unsuitable for Balfour's operation, by reason of the size or remoteness, or deep perforation of the ulcer; and for the operation of gastrectomy by reason of the extremely feeble condition of the patient, who has perhaps recently suffered from a copious hemorrhage. In all such cases I perform gastroenterostomy in "Y," generally by the anterior route. The intestine is cut across about 12 to 15 inches below the flexure, the distal end closed, and the side of this distal part united to the anterior wall of the stomach. As large an opening as possible is made proximal to, or in the zone of, the ulcer, and extending sometimes over the fundus of the stomach. The proximal divided end of the jejunum is then anastomosed to the side of the distal limb a few inches below the gastroenterostomy opening. Into this proximal part at a point about three inches above the junction which has just been made with the distal limb a tube is introduced and fixed by the method of Witzel. The tube passes for several inches down through the enteroanastomosis into the jejunum. It is brought out of the abdominal wall through a small separate incision to the left of the umbilicus. It is through this tube that all nourishment is given for months, or for years, until a radiological examination shows that the ulcer is healed, and until a trial then of one month, during which food is given, discloses no return of the symptoms. During this time the greatest care is taken to keep the mouth clean by friction, the use of chewing gum, and frequent washing. I have never had any difficulty with a patient craving for food. The sufferings endured before operation and the relief immediately afterward, by their sharp contrast, make the patient disposed to do all one asks. One patient whose stomach showed the largest ulcer I have ever seen (we described it as resembling the mouth of a letter box through which the hand passed deeply into the liver), took no food for two years and nine months after this operation, although I gave her permission to do so. She took food generously through the tube and gained over 50 lb. in weight. Since removing the tube, now a few years ago, there has been no recurrence of symptoms. Indeed, up to the

present time, in no case in which this operation has been practised has the ulcer returned.

5. *Median Resection of the Stomach—Sleeve Resection.*—This method enjoyed a great vogue in many clinics, but its end results were not satisfactory. Contraction at the suture line followed in many instances and necessitated further operations. Kummell in ten cases found that in all an hour-glass stomach was produced; and Faulhauer and Redwitz in their experimental work found that in every instance tight constriction of the body of the stomach was caused when healing was complete. The method is one I have not performed for many years.

6. *Partial Gastrectomy.*—My experience of these operations has led me by degrees to abandon all of them except that in which gastroenterostomy is combined with jejunostomy. For a great variety of adequate reasons I think it is safer to be rid of the greater part of a stomach in which a gastric ulcer has formed. If for any reason removal is impossible, then the combined operation of gastroenterostomy and jejunostomy allows the ulcer tissue time to heal while the feeding of the patient is continued.

My choice of operation, therefore, now always falls upon partial gastrectomy, whenever it can with reasonable safety be performed. The risk is not great: over a period of ten years it is less than 2.5 per cent. All things considered, and account being taken of the five years succeeding operation, it is probably a safer operation and is certainly more immediately satisfactory than gastroenterostomy alone. It cannot always be practised. The condition of the patient may forbid it. The ulcer may be so large and so placed as to make removal a matter of so great technical difficulty that the immediate hazards are unfair to the patient. But as experience grows the number of such cases diminishes. Nowadays I rarely practise any other operation than partial gastrectomy or my own method of gastroenterostomy in "Y" combined with jejunostomy. The details of the operation of gastrectomy are briefly these: the duodenum is divided just beyond the pylorus, after ligation of the pyloric and gastroduodenal arteries. An opening is made in the transverse mesocolon, in the arch of the anastomosis of Riolan, in order to guide the surgeon in his ligation of the omentum below the greater curvature, so that the middle colic artery may be avoided, and in order that the conditions at the back of the stomach may be early and fully investigated. After division of the great omentum as far toward the left as the point at which the stomach is to be divided, the whole organ is turned over to the left edge of the parietal wound, until the coronary artery is brought into view and ligatured with great ease at exactly the place required. As soon as this vessel is cut an anchor is "let go," and the stomach is moved more freely. Then, while the stomach is held as a retractor, an anastomosis is made between it and the jejunum. I now always apply the end of the stomach to the side of the jejunum.

In my early cases I twice encountered a little difficulty in making the jejunum so apply itself to the stomach as to avoid a kink at the upper end of the anastomosis. In both cases some bilious vomiting occurred. In order to prevent this I now usually divide the jejunum completely across, about 6

or 8 inches below the duodenojejunal flexure, close the distal end, apply the side of the closed distal end to the cut end of the stomach, and then unite the proximal cut end to the side of the distal end about 4 inches below the stomach, thus making an anastomosis in "Y." This takes a few minutes longer, but the expenditure of time is worth while. Time is saved when the stitches which close the opening in the mesocolon are applied round the suture line; by this method they are easily and quickly inserted. The results are excellent. The condition after operation is remarkably good; in almost all cases the patients have the most tranquil progress that one could wish. And not one single case I have ever operated upon has had a recurrence of the ulceration. Once the convalescence is complete the history is without incident.

Whatever the operation from among all those mentioned which may be selected in each individual case, regard must always be paid to the power of the patient to bear it, and to its exact application to the particular conditions disclosed when the parts are directly examined. Before the operation commences the surgeon should never reach a definite decision to perform any one procedure; he must apply at the moment of operation the method which best meets the indications in each case. And here, as elsewhere, the little things count. Care in preparation, scrupulous exactitude in every detail, gentleness, deliberation, with such speed as comes naturally from much practice and is unsought as a special feature, all these together will sometimes turn what would otherwise be failure into easy and certain success.

My record of cases since 1909 is as follows:

Gastrostomy	96 cases, 2 deaths = 2.08%
Gastroenterostomy:	
Posterior	701
Anterior	8
In Y	13
Author's operation, gastro-	
enterostomy in Y with	
jejunostomy	14
Gastroenterostomy in Y	
with gastrostomy	2
In many cases the appendix	
was removed, and in some	
the gall bladder drained or	
excised. In two cases ovar-	
ian cysts were removed also.	
Excision of gastric or duodenal	
ulcer with or without gastro-	
enterostomy including Bal-	
four's operation	43 cases, 1 death
Hourglass stomach, treated by	
multiple short-circuiting opera-	
tions; gastroenterostomy com-	
bined with gastrogastrostomy,	
etc.	19 cases, 1 death
Jejunostomy	4 cases, 1 death
Total	316 cases, 12 deaths = 3.8%
or excluding 22 cases of gastric	
ulcer in which there were	
two deaths, the total number of gastric and duodenal ulcers	
is 375, with 10 deaths, a mortality of 1.11%.	

HORMONES AND EMOTIONS.*

By SANTE NACCARATI, M.D., Sc.D.,
NEW YORK.

THE clinical and experimental researches of the last twenty years regarding the glands of internal secretion have notably contributed to medicine and to biological sciences in general. Notwithstanding the great difficulties presented by the study of these glands, and the many points of obscurity that still remain to be cleared up in regard to their function, endocrinology acquires constantly greater importance, and is becoming a separate branch of medicine, with periodicals of its own.

*Read before the Italian Medical Society of New York.

It may be said that there is no subject which has claimed more attention, and which today is more discussed in speech and in writing, than that of the endocrine glands. The discussion is so suggestive that it often departs from the medical and biological field to interest the psychologist, the sociologist, the philosopher, the educated public, and even those persons whose education and whose intellectual capacity are not above the average.

Last year the account of the experimental researches in regard to the thyroid gland conducted by Voronoff, made the round of the French and Italian newspapers, according to which Voronoff succeeded in restoring youth to aged animals by injecting into them the thyroid of young animals; thus the thyroid came to represent, for the public, a sort of elixir of life. An English translation of Voronoff's work has now been published in America.

Soon thereafter it was the turn of the English newspapers, which announced extraordinary results attained in the laboratory at Oxford by T. S. Huxley, nephew of the great zoologist, T. H. Huxley.

According to these newspapers, the results of experimental research in the laboratories at Oxford and Liverpool show the thyroid to possess the properties of renewing vital energy, of determining sex, and of regulating growth.

Huxley's experiments deal chiefly with the metamorphosis of tadpoles, which is retarded by the removal of the thyroid and hastened by the administration of thyroid substances; also with the transformation of the Mexican batrachian *Axolotl* into the American salamander *Amblystoma*, a transformation which is assisted by subjecting the animal to forced respiration, but still more by administering bovine thyroid.

As is well known, the experiments of Huxley which so greatly excited the English press are in no sense a scientific novelty. For years past the same questions have occupied Goudernatsch, Allen, and others in America, Boulanger, Kollmann, Chauvin, Jensen, Vaillant, Perier, Vecchi, Cotronei, and others in Europe.

The publication of the results of Professor Steinach's experiments with the "puberty glands" gave also the German press, both in Austria and in Germany, a pretext for reporting sensational accounts and raising false hopes among the laity on the matter of "Rejuvenation of the Aged." Steinach's grafting experiments were made on old impotent male rats, some of which became sexually potent and procreative, and on two old men, aged 65 and 71, who two months after operation lost the characteristics of senility and regained vitality and sexual vigor.

Reports of this kind are becoming rather frequent in the daily papers of every nation. This accounts for the interest which the laity takes in biological problems connected with the endocrine glands.

The results thus far obtained are far from justifying the extreme statements made by the press. Endocrinology is still a young science, and as such is full of uncertainties and of unfilled gaps which, while for the true scientist they represent a field of research, represent for the amateur a fertile field for the wildest speculations and hasty conclusions with which to fascinate and delude the lay public. Unquestionably a careful study of the endocrine glands will reveal to us the now hidden

solution of many biological problems. Such studies require fewer hypotheses and more experiments, although we are aware of the fact that hypothesis and theories are the yeast of science when timely and properly advanced. Charles Nordmann¹ in a reviewing article on this subject has put forward the hypothesis that variations of species are to be accounted for rather by the endocrine glands than by the environment, as supposed by Lamarck. An accidental disease of an endocrine gland, resulting in a suppression or increase of its function, might produce profound modifications in the morphogenesis of the animal, as in the case of Axolotl, which undergoes variations of species. This hypothesis, however, forgets that the inheritance of acquired characters is still far from having been demonstrated.

A most suggestive problem which is being followed with keen interest concerns the relation existing between the emotions and the internal secretory glands. Notable experimental contributions to this subject in this country have been given by Crile,² Cannon,³ and many others. Cannon and his school claim to have demonstrated that there exists a close relationship between certain emotions and the secretion of adrenin. Although Stewart and Rogoff⁴ have contradicted many of the assertions of Cannon, it cannot be denied that Cannon's work has opened a new field for psychological as well as physiological experimentation. We do not possess as yet laboratory methods for the isolation and study of the hormones of the endocrine glands with the exception of adrenin; nor do we possess laboratory proofs that certain hormones are increased or decreased in some abnormal psychic states. However, we possess many clinical indications which tend to confirm that not only the adrenal glands but the whole endocrine-sympathetic system is upset in disturbances of the emotional life.

Laignel-Lavastine⁵ and others quite often found thyroidal and ovarian disturbances among hysterics. Levy and Rothchild⁶ call the thyroid "the gland of the emotion" because of the active part which it plays in regulating the nervous mechanism of emotional discharge and its external display. In fact, the manifestation of some emotional states—fear, anxiety, worry, despair, intense expectation—corresponds to the symptoms found in diseases in which the thyroid secretion is in excess, viz.—frightened appearance, exophthalmos, tremor, tachycardia, dyspnoea, vasomotor, and secretory changes of the skin. Other authors called the thyroid "the gland of intelligence," because its secretion seems to stimulate the intelligence. We think that in hysteria, in anxiety neurosis, and in all the so-called emotional psychoneuroses, definite disorders of the thyroid and adrenals exist, to speak of only two glands, whose symptomatology is better known.

The essential characteristics of hysterics are: instability, suggestibility, hyperemotivity. The last one is responsible for the other two. These manifestations are found mostly among women who are more unstable, suggestible, and emotional than men. Such peculiarities of women must be connected with the variability of the thyroid function produced by the periodic changes of the sex glands whose hormones are in intimate functional relationship with those of the thyroid. In normal children before the

appearance of secondary sex characteristics there is no marked emotional difference between the two sexes. Mild nervous symptoms of hysteric character are found in children in whom a state of thyroid dysfunction exists, which Levi and Rothschild call "hyperthyroid temperament." These children are very unstable, irritable, highly emotional, subject to excess of anger, laughter, crying, peevishness, and at the same time show a certain degree of vivacity and intelligence. In physiologic states corresponding to certain periods of development or morphological changes of the organism, in which we know the thyroid and other glands are called for a more active function, we find a suggestion of the same nervous symptoms, e.g. at the seventh year of age and at adolescence in males and during the premenstrual periods, pregnancy, and the preinvolutional period in females. Typical hysterical symptoms may appear during those periods in normal women, while the same are increased in women already suffering from hysteria. For this reason hysteria was formerly alleged to be dependent upon disorder of the ovaries by some gynecologists who advocated different operations, but with negative results. At that time hysteria was considered almost exclusively a disease of women.

We cannot dwell too long on the many theories concerning the genetic mechanism of the emotions. The conception expressed by James and Lange in their somatic theory appears so much greater today inasmuch as practically nothing was known at their time of the relationship existing between the central nervous system and the endocrine-sympathetic system.

We think that emotion is the expression of hormonal actions. Emotions start very early in life and are coupled up or attached to the instincts by means of the endocrine secretions. In virtue of this early association or attachment, emotion becomes an instinctive reaction and is excited by any situation in which the gamut of the instincts is called into action. Conversely emotional states reinforce the instincts and tend to discharge themselves through the instinctive reactions. At first it would seem that each emotion is the manifestation of the hormonal activity of a particular gland and is attached to a definite instinct. The emotions of fear and, in a measure, anger seem to be attached through some of the hormones of the thyroid to the instincts of self-preservation and somatic integrity; the emotion of love (sex of the Freudians) seems attached to the instinct of preservation of species, through sex glands; anger seems more attached to some hormones of the pituitary. But it is not so. All the internal secretory glands together with the sympathetic nervous system are at the bottom of the emotional life. The organic reaction which accompanies the emotion is probably the same in quality in all the emotional states; what varies is the intensity and the duration. The different names created for so many emotional states are artificial inasmuch as they indicate objective states; in the same way as the old psychologists used the term "faculty" to indicate performances or phenomena corresponding to what seemed to be a particular mental activity. Who can draw a line between fear and anger in some of our subjective states? Cannon has taken only a relatively

small fraction of the organic manifestations which take place in anger, fear, hunger and pain, but we must not consider that fraction as the whole of a by far more complex mechanism.

It is known that there exist innumerable interrelations among the hormones of a same gland and among these and the hormones of other glands; these interrelations explain why all emotions may be aroused even when one or more endocrine glands are removed. It is true that in such instances the peculiar emotional responses are greatly diminished. In fact when the thyroid is removed a state of apathy follows which is characterized by slow ideation, late perception, poor imagination, aboulia, drowsiness, and great diminution and even loss of reaction to emotion. The same apathetic state is encountered when the pituitary is removed as well as in nearly all the well known syndromes due to insufficiency of parathyroids, sex glands and adrenals. Demonstration that such a state is due to the absence of hormones and not intoxication of the brain centers by substances which were not neutralized, is given by those opposite conditions in which an excess of internal secretions is known to exist; *e.g.*, witness the exaggerated emotional reaction to fear, worry, and anxiety, the live ideation, the prompt perception, the hypersensitiveness to sensory stimuli, the restlessness and instability met with in cases of hyperthyroidism. Some authors explain the mental deterioration consecutive to removal of thyroid as a myxedematous infiltration of the brain, but while the brain edema and its deleterious influence cannot be denied, it must be granted that the infiltration starts after the mental dullness has already begun; therefore, in the first period of athyroidism the mental symptoms are due to lack of hormonal stimuli.

The objection of those who attribute the mental symptoms of athyrosis to inadequate general nutrition of the organism and consider the mental symptoms secondary and consecutive to the physical ones, cannot be accepted in the case of adults. Here we have organisms which have reached their full physical and psychic development; therefore, arrest of growth cannot be taken into account for the disorders of the psychic sphere.

Von Monakow⁸ says that the internal secretory glands influence the nervous system in general and the sympathetic in particular, and so provide a diffuse mechanism which regulates the vegetative or instinctive life of the organism. He thinks that moral traumata, severe psychic conflicts, unsatisfied strong instinctive tendencies, produce functional disorders in the endocrine glands through the sympathetic system. This is followed by biochemical changes in the blood, which, combined with the protracted psychic stimulation, produce nervous disorders which constitute neurasthenia, hysteria, phobias, and hypochondriasis.

In mild emotions in which the connection with an instinct can hardly be detected, the hypersecretive stage must be short and so inconsiderable that the corresponding increased brain activity does not appear. Thus behavior seems not at all influenced. From such mild forms of emotion in which secretion is scarcely affected, we pass through a long series of graded strong and violent emotions which may be the expression of ever-increasing secretory actions.

The more the secretion which the strong stimuli call for, the longer will last the repercussion on the behavior, as any abnormally increased secretive state tends to pass from a transitory stage to a permanent one. It is almost the same thing which happens in the case of a rubber band. Gentle tractions will not produce any permanent changes in its shape and dimensions, but continuous strong tractions will produce each time a weakening of its inner resistance, a diminution of its power of contractibility and retractibility, and consequently it will tend to assume a permanently altered shape and dimension corresponding to the traction exerted.

"Every emotion leaves a sequel, an affective print, an orientation more or less definite, more or less durable, of the moods which cannot disappear with the ease and with the promptness of the representations of the provoking happenings. Hence a parallel orientation in the conduct. . . . This influence of the moods and of the prolonged protracted emotions on the motivation of the consecutive acts, influence which is due to the blind somatic mechanism of the emotions, suffices to explain, without the *deus ex machina* of a psychic unconscious, the phenomenon of *conversion*, which Freud puts as a base of his doctrines, or at least many of them." But what is the energetic factor of the affective tension which follows the emotion? A psychic manifestation is of course the transformation of another action, physical, chemical, biological; in the same way as an electric current or a magnetic action, a protracted light or sound sensation cannot exist independently from a still active physical or chemical stimulus. The laws of preservation of energy, of transformation of matter, the laws of action and reaction, cause and effect govern also the biological as well as the physical and chemical phenomena. An emotional state which continues to exist long after the removal of the sensitive or representative stimulus indicates that there is a physiological action or some irritation somewhere within the organism. This action, this irritation, or, to use an appropriate term of Woodworth, the originator of the dynamic psychology, this "drive," must be kept on by the hormones or by unknown substances set free by the hormones during the emotional discharge. The emotional experience will drop out of consciousness and memory, but the hormonal action will outlast it and will have impressed a durable course to the behavior, thus causing incongruous external manifestations which are usually attributed to the blind activity of a subconscious life.

The hormonal "drive" which is so frequently the mischief-maker of many pathological manifestations in the field of thought and action, is also very frequently the generator of many useful and genial activities. We all know the great part emotion has always played in historical events and in the great achievements of human progress. A life without emotions would be a life without action. The history of art and literature shows how many masterpieces were inspired by the emotion of love. Probably a well-coordinated and well-balanced hormonal flow due to an emotion equals *inspiration*. Hormonal actions must probably take place in human *intuition*, which Bergson¹² keenly compares to animal instinct. Thus the creations of geniuses in arts, science, and literature may have some rela-

tions with the hormones. Apparently it would seem that the cold man of science has no emotion which may be accounted as driving force for his discoveries. But this is not true. He has the interest, the expectation, the determination, the ambition which act as protracted emotional states in keeping on the harmonic flow necessary to the productive activity of the brain. As Woodworth² observes, "Anger, zeal, determination, are closely allied and probably identical in part. Certainly they are aroused by the same stimulus, namely, by obstruction encountered in the pursuit of some end."

Probably with the same mechanism of physiological hyperactivity of some hormones must be explained the sudden exhaustion of the so-called *enfants prodiges*, who during adolescence show signs of unusual intelligence and promise but afterwards barely reach the mark of mediocrity. For some unknown reasons, a state of hyperactivity of some psychostimulating hormones surpassing a great deal the physiological limit of that age, appeared at the time when many endocrine glands are called for more function, but such a state is like the apparition of a luminous meteor. Sometimes those same subjects, who were plumed for geniuses, may develop some sort of degenerative or constitutional psychosis, because to the period of abnormally increased harmonic production another period of marked hypoactivity or alteration of the same hormones may follow.

Emotions are original tendencies only in the sense that they are early attached to the instincts. There is no definite time in which each emotion makes its first appearance in the child. Without the occurrence of a certain situation, the emotion could not appear, and many times observers of children's behavior have failed to detect the first situation which made the earliest connection, and called original a response which was acquired after a series of similar situations, of which they saw only one of the later, and erroneously considered it the first one. We agree with Bechterew's idea of conditioned reflex, inasmuch as the emotional response is conditioned to a situation which calls for some internal glandular hyperactivity. The fear response is not provoked by the situation "a variety of objects and sense impressions which is difficult to discover," as McDougall says, but which experience suggests a personal danger. It is danger calling for the instinct of self preservation which acts as conditioned reflex in setting up the harmonic drive that gives the fear response. The child is not instinctively afraid of the dark, as most psychologists think; it shows the fear response to such a situation only when the darkness has become a conditioned reflex for the said emotion. Powerful instincts which come into action at the first indication of the individual's danger set up the harmonic drive, such indication being supplied in the earliest moments of life by some sensations of which we do not know the essence or the action. From that moment the fear response will follow the situation darkness until we are able to detach such emotions from such situations through training by attaching it to other pleasant situations in the dark. The new situations will gradually eliminate the element of danger, which first set up the harmonic drive by calling upon the corresponding instinct. But usually in adults

the situation darkness is followed by a fear response, because it implies the idea of danger.

The first fear and anger responses of a kitten to the situation "dog" are original, inasmuch as the instinct of self preservation which warns the animal of the immediate danger (olfactory stimulation probably) must initiate the harmonic drive. But the response of anger to the situation dog can be detached, if the cat is allowed to grow up with the dog, and thus is given opportunity to convince itself that the dog is not a danger to its life.

The sight of an aeroplane, the whistle of a siren, the ring of bells did not provoke any fear responses before the war. They provoked curiosity, wonder, interest. During the war, however, these same stimuli provoked strong fear responses, because they were associated with the aerial bombardment whose consequences called for the most powerful of primal instincts common to men and animals.

Emotions, having their physiological seat in the endocrine-sympathetic system, are involuntary, automatic, instinctive; they are unconscious when they start, and become conscious only when the centripetal harmonic stimuli reach the brain centers. But as the will tends to take control of the instincts in human ontogenesis, so training and the superior feelings which appear later (altruistic, social, esthetic, etc.) tend to inhibit or to discipline the emotions by rendering them independent of the instincts, namely by detaching them from the instincts. That is the reason why educated persons who possess such feelings, and have developed orderly habits of reflective thinking, are seldom dominated by the emotions as are children, intellectual inferiors, uneducated, infantile, and senile types of individuals in which every emotion finds an outlet through instinctive egoistic reactions. It is easy to understand why these infantile and inferior types are those who will react more promptly in a pathological manner to strong emotions. War experience demonstrated that among officers the emotional neuroses were less frequently met than the asthenic forms; the opposite was found among troops, who are usually less educated than officers.

In normal individuals an ordinary emotion of fear or anger produces a very short hypersecretive state, a stronger emotion is followed by a longer period of hypersecretion, but the interharmonic equilibrium is soon restored. If it is not restored, either on account of the extreme violence of the emotional stimulus or on account of its unusually long duration, or because of lack of resistance of the subject, nervous symptoms will ensue, which will have in an enlarged scale manifestations as manifold and various as the many reactions met with in ordinary fear responses. If we compare these with the many hysterical manifestations, we will see that the latter are merely the correspondents of the former enlarged in dimension and prolonged in duration. Aproxia, which is met so frequently in severe emotional syndromes, is nothing else than the continuation or the fixation of the responses "withdrawal of attention from everything save the exciting situation." Hysterical paralysis, astasia-abasia, correspond to the fear responses "falling down, remaining semiparalyzed, remaining stock-still." Convulsion, tics, spasms, are the correlative of the responses, "trembling, shuddering, shiver-

ing." "Blindness, mutism, deafness, anesthesia and analgesia are the continuance of the magnified subjective sensations experienced at the time of the emotion, viz., darkness of the visual field, tightness of the throat, and inability to utter words, paracusiasis, feeling of numbness, and insensitiveness to pain.

Those who ask why it is that hysterical symptoms are so manifold and so variable even in the same subject under different circumstances, find an answer to their question in the original nature of man, which has provided for hundreds of different responses to the same situation. In the matter of instincts we know that the instincts have not the same dominancy in different people. Apart from the individual deviations and variations due to nurture, this is true even with the strongest and the most primal instinct, "the will to live," which Schopenhauer considered as the metaphysical principle of the universe. Genetically the emotion of fear originated as a useful reaction intended to warn the individual whenever the attachment to life, "the will to live," "the joy of living," is menaced, in order that he might bring into action all his "reservoirs" of power, to use an expression of William James, against such menace. For instance, in battle we find all the elements indicating that such a menace is imminent and effective; there many and extremely frequent are the situations producing fear responses. In such circumstances the endocrine sympathetic system is kept under a severe stress, but as long as its physiologic limit of resistance is not surpassed, the emotional responses do not take a pathological course. Once, however, an unusual situation or a series of situations arises, this being beyond the individual's expectation and resistance, more or less permanently breaks up the endocrine equilibrium and so upsets the whole mechanism of the emotion. From this moment a permanent emotional period corresponding to the hormonal dysfunction and to sympathetic irritation, starts and continues until the equilibrium is restored again. This period will characterize the emotional psychoneurosis during which the personality will lose control over the emotions; strongly repressed infantile instincts and impulses will break through and we shall witness a sudden reversion to the stage of mental childhood. In this stage, in the same way as the subject has become the toy of emotions, he will become also the victim of the suggestion of other people or of his own. Moreover, the facility by which the emotions are formed and are let govern the actions, will consequently lead to the formation of the particular unstable character which plays such a prominent rôle in hysteria.

When after a strong emotion the endocrine equilibrium has been disturbed, this may be gradually restored by the natural resources of the subject, without any therapeutic intervention. In this case the time for the complete functional *restitutio ad integrum* of the endocrine-sympathetic system is dependent on the intensity, quality, and duration of the emotional trauma and on the individual constitution. If the natural resources are insufficient to obtain the *restitutio*, it will be obtained by means of psychic stimuli which should counteract or neutralize the action of the emotion responsible for the

breaking-up of the endocrine equilibrium. It is obvious that such state of dysfunction may continue to exist even if the emotional experience is not known or has been forgotten by the patient, causing those functional disorders of the nervous system of which we are unable to discover the origin or the motivation. This well-known process of forgetfulness which is due to the physiologic mechanism of the gradual obliteration of the mnemonic impressions and to the superposition of new ones, has received the name of "repression" and is considered by Freud as a mental mechanism. An inference which seems opportune at this point is that so many sexual complexes found by the psychoanalysts in neurotic women are nothing else than artificial productions of their own imposed on the minds of weak plastic personality open to suggestion and eager for recovery. Speaking from a strictly psychological standpoint, the good and original in the Freudian doctrine has been greatly abused and misinterpreted, especially in this country where Freudism has been blindly accepted and has received a much larger advertisement than in the country of its origin. The whole group of concepts—the "unconscious," "repression," "sublimation," "conversion," etc., with the exception of the "*Uebertragung*" (attachment and detachment of the emotion) are not new acquisitions of psychology; they are old ideas expressed with new terms taken from chemistry, physics, physiology, and other sciences.

We meet every day with cases of neuroses which recover either without or with psychotherapeutic procedure and also with individuals who wander from the office of the psychoanalyst to that of the Christian Scientist. In the first cases, viz., those who recovered without treatment, the environmental and the inner conditions of the patient sufficed to restore the normal function to the deranged endocrine-sympathetic system; in the second, viz., those who recovered after treatment, the normal function was restored by emotional psychic stimuli; in the third, viz., those who didn't recover at all, morphological and structural changes had occurred within the endocrine-sympathetic system following a long period of dysfunction, therefore nothing could reintegrate the lost equilibrium. When further researches enable us to discover such fine anatomical or biochemical changes within the endocrine sympathetic system, many of the so-called functional cases will be classified among the organic. We explain the successes obtained through psychoanalysis or through other psychotherapeutic procedures as due to the reestablishment of the endocrine equilibrium and of the normal sympathetic function, by means of psychic stimuli. Thus we explain also the relapses of those hysterics whom the psychoanalysts have pronounced definitely cured. These subjects, having a very unstable endocrine sympathetic system, offer limited resistance to emotional traumata, which will once again produce more or less temporary disorders of secretive nature within its chain and lead to the same neurotic symptoms or to different ones.

In conclusion, in matters of emotional traumata there are four elements to be considered: (1) the quality of the emotional stimulus; (2) the intensity; (3) the duration; (4) the endocrine-sympathetic make-up of the subject. Regarding the first

three elements, we know how variable they are. If we were to make a graded scale of the emotions containing these three elements, we would have a very long list and would convince ourselves of the extreme rarity of meeting with two identical situations containing the said elements in the same proportion. In war and in some of the collective disasters in civil life, we have examples of groups of individuals exposed to the same emotion in which the three elements of quality, quantity, and duration are practically equal. The fourth element varies in individuals and is the one responsible for the behavior at the time of the emotion and for the diversity and duration of symptoms later. When the endocrine system is thus upset, a more or less long period of dysfunction follows, during which, if it lasts too long, structural changes within the endocrine glands may occur. Such anatomical changes may be macroscopic, as in Graves' disease,* or they may be such as to escape detection. To such changes must be attributed those chronic cases of so-called functional nervous diseases which never yield to treatment, and are bound to continue throughout life. A practical point which comes from this consideration is that during the period of dysfunction of the endocrines and before structural changes have occurred, the treatment should be conducted in order to obtain successful results. This is the period of greater plasticity or permeability of the endocrine system and, consequently, also of the nervous system in general. If the psychic and physical treatment is not applied in time, then the endocrine-sympathetic dysfunction tends to assume a permanent course, either for the law of adaptation to which man is subjected as to the laws of habit, exercise, and effect; or because of structural changes which occur within the endocrines.

Predisposition to psychoneuroses really means an instability, inherited or acquired, of the endocrine sympathetic system. Neurotics in general and hysterics particularly are individuals possessing a labile endocrine system whose equilibrium may be broken at any time by a strong emotion and upset when submitted to the continuous emotional "surmenage" of a too intensive life.

PETROLEUM GAS POISONING.

ESPECIALLY IN THE MEXICAN FIELD.

BY DOUGLAS BROWN, Ph.B., M.D.,

NEW YORK.

No medical man can be long in the vicinity of the Mexican oil fields without the arousing of his curiosity as to what the frequently mentioned "gas poisoning" really is. Especially after experience on the Western Front, the reports of sudden loss of promising young lives lead to investigation of what it is, what it does, and the possibility of devising practical methods for resisting its attack.

At a recent meeting of the Committee on Safety and Sanitation of one of the larger oil companies, the question arose as to which gas was the more poisonous, natural or illuminating gas. The answer was illuminating gas, and was based on the analyses of the two as found in Pittsburgh by G. A. Burrell of the Bureau of Mines.

To get a basic idea of the components of some of these gases, the analyses of these follow:

Natural Gas:	
Methane (CH ₄)	84.7
Ethane	9.4
Propane	3.0
Butane & C.	1.3
Nitrogen	1.6
Carbon Dioxide	A Trace
Illuminating Gas:	
Hydrogen	37.0
Methane	31.0
Carbon Monoxide	13.3
Illuminants (C ₂ H ₂ & C)	8.7
Nitrogen	4.8
Carbon Dioxide	2.6
Ethane	1.3
Oxygen	0.8

In mines the danger from methane is the danger from explosion and dilution of oxygen inhaled. An atmosphere containing 0.25 per cent. carbon monoxide inhaled for twenty minutes produces impaired sight and hearing, staggering, confusion of ideas, with nausea and headache lasting twelve hours, while 10 per cent. CO₂ is necessary to cause symptoms of marked distress (heavy panting, palpitation, flushed face, stupefaction and severe headache). Methane is known as "fire damp" and is guarded against by the "cap" on the safety lamp flame.

Carbon dioxide (with nitrogen) is "black damp." Carbon monoxide is the "white damp." A canary collapses in eighteen minutes in a 0.15 per cent. carbon monoxide atmosphere and shows signs of distress in three minutes. If the gas contains any

of the sulphur combinations (0.05 per cent. in air of H_2S , SO_2 , or CS_2)—there is immediate distress in canaries and mice. Hence the lamp and canary carried into the mine. All this has a bearing on an analysis of gas poisoning later on.

Now if the question asked had been: "Which is the more poisonous, illuminating gas or the natural gas from the Mexican oil fields below Tampico?" the answer would have been "Mexican gas," emphatically. Cattle, horses, burros, mules and men are felled by some of it as by an axe. In the petroleum industry danger lurks from the well to its final consumption. The giant wells of the "lower" fields, near Tampico, Mexico (about Tepetate, Obando, "114," etc.), have been born under very high pressure. The wells in the Mexican field about Panuco have not as impervious a super-stratum, there is less pressure, and the gas is distinctly less toxic; the final product of the latter is asphalt, and of the former frequently a paraffin base. A gas from wells of the lower fields is especially toxic; one inhalation and consciousness ends. The gas from these giants has become ignited, burning for weeks before controlled, and lighting up miles of the surrounding country with a light much brighter and purer than that from the gas of the "upper" fields. The pressure of the released oil, and the birth of gas through the volatilization of certain components by the release from pressure, is enormous. They pour out 100,000, 200,000, even 300,000 barrels a day of "Mexican Crude." It is free from sand and is, therefore, capable of control by valves in spite of the pressure; an oil pump is unknown in the Mexican fields. But there are, of course, leakage and frequent tragedies. The necessity of reducing this mortality led to an investigation of work done on petroleum gas poisoning. It was noted (as far back as 1872) that there was a difference in the physiological effects of different kinds of petroleum¹ and Sharp² summed up the situation by stating that the difference in the effect of American petroleum on the workers was due to their different compositions. Where natural heavy oils were obtained, asphyxia from gas was unknown, whereas with light oils suffocative attacks may not be infrequent. Some petroleum, it was found, irritated the respiratory passages, while others affected the central nervous system. Scheller and Strauss³ reported carbon monoxide as the cause of death of a man repairing a leak in a still, from its presence in the gases, resulting from the distillation of *petroleum residues with a paraffin base*. But on a tanker, carrying Mexican Crude with a paraffin base, escaping gas was detected. The man sent below did not return, the man that went after him did not return, and, when the third failed to return, they left the bodies there until sufficient ventilation made removal safe. These men died suddenly and without any outcry, not from any carbon monoxide asphyxiation, but probably from the same intensely toxic gases that overwhelm the medullary centers of workers in the lower field.

The carbon monoxide idea was followed up. Its amount in the distillation of crude oils from different localities varied from 1.1 to 8 per cent., and Scheller and Strauss assumed its origin from the decomposition of acids and esters in the residues.

A further analysis of the gases from the distillation of lubricating oils gave the following results:

	Soon After Beginning Distil- lation	After 1 Hr.	After Distil- lation of 1/3	End of Distil- lation
	Per Cent	Per Cent	Per Cent	Per Cent
Carbon dioxide	3.5	6.0	3.0	2.5
Carbon monoxide	16.0	8.5	16.5	10.0
Unsaturated hydrocarbons	3.5	12	3.5	16.5
Saturated hydrocarbons	77	73.5	77	71.0

Refined machine oil yielded no carbon monoxide, but the introduction of air, during distillation, caused the formation of CO_2 . This would be expected, as the reaction of the hydrocarbons, as well as carbon monoxide, with oxygen is CO_2 (and H_2O).

We have reports of poisoning from inhalation of benzene and gasoline.⁴ These range from primary cerebral stimulation (intoxication) to death. Symptoms of chronic poisoning may arise especially among the women workers with benzene. The Union of Chemical Industry in Germany (1905) reports two fatal cases in connection with naphtha stills. This must have been due to insufficient disconnection of the still and the passage of noxious products of distillation backward into the open still, where the men were working.

Rambousek's cases of fatality from benzene he thinks probably due to hydrocarbons of low boiling point present as impurities in the benzene (not benzene).

It is not until we reach the report on the Lima-Indiana and Gulf fields, and the distillation of these sulphur crudes,⁵ that we find a markedly more lethal emanation that requires the greatest confinement possible.

Symptoms.—Poincaré⁶ calls attention to the inhalation of the volatile constituents of crude petroleum in the air, producing symptoms affecting mainly the central nervous system, while some have a markedly irritating effect on the respiratory tract. Further, hydrocarbons boiling at low temperature act as nerve poisons, whereas those boiling at higher temperatures produce the local irritation.

The symptoms may be very acute and promptly fatal by overwhelming the cerebral centers, and from this it grades down to a simple stimulation of the higher centers, and the worker will tell you that the feeling is enjoyable and similar to primary alcoholic stimulation. Others are calmed, as from an opiate. Gowers⁷ describes *chronic poisoning* with slurring speech, difficulty in swallowing, vertigo, general nervousness, tinnitus aurium, hallucinations, loss of memory and anemia. Interest arises as to the possibility of lenticular softening, similar to that found in carbon monoxide poisoning. Intrinsic poisoning (toxins) may enter into these cases, though we are dealing with the poison as *extrinsic* only. Idiosyncrasy, however, may play a part in increased susceptibility to inhibitory influences, leading to partial or complete heart block or even ventricular fibrillation. There is also the *local skin effect* noted among workers on unpurified oils, liquid petroleum and its semi-solid and solid residues after distillation, and paraffin. Eruptions, papillomata (warty), acne ("paraffin eczema"), and a pustular eczema of hands, face and ears, also even abscesses and ulcers.⁸

Thompson⁹ mentions similarity between naphtha poisoning and benzol poisoning. He states death

may result from hemorrhage from the respiratory mucosa or paralysis of the heart. Autopsies on cases lasting a few days show fatty degeneration of heart, kidneys, and liver.

According to Jaffe,¹⁰ benzene is chiefly, if not entirely, excreted through the lungs, and when the process of resorption and excretion is rapid, extensive pulmonary hemorrhages are found. Resorption through the stomach, though slow, leads to extensive necrotic and inflammatory changes in the lungs.

It has been found that 0.05 gram of benzene per liter of air is poisonous, while 0.02 gram per liter causes local symptoms. It is well to call attention to the danger of poisoning also from poor combustion of any gasoline engine working in a poorly ventilated structure. With good combustion, the CO₂ is (approximately) three times the CO, but with bad combustion the CO is three times the CO₂—in cubic feet given off.

A man prostrated by "Mexican Crude" gas is pale, not cyanotic. The surface of body tends to be moist and clammy. The expression is staring. The pupils may be somewhat dilated or unaltered. The muscular system is relaxed. The breathing is superficial or suspended, heart action laboring and slowed, and pulse almost imperceptible. There is no irritation of respiratory mucous membrane then or later in case of recovery.

Affected to a less degree, some men suddenly feel that the knockout is coming, and on recovering consciousness find themselves with their arms extended, running excitedly across the open country, yelling or laughing hysterically. Their ideas are confused for several minutes, but there is no respiratory or cardiac distress. A headache may follow. There may be also a conjunctivitis.

Legludic and Turlais¹¹ state that the heart action of dogs on inhaling the gas was increased in force and diminished in frequency. If the gas is pushed, the heart stops in diastole. The action is through the vagi, as proved by their section.

Treatment.—The protection against poisoning has been the employment of a mask, with attached tube leading from clean air. In a case of prostration, the man is carried to good air, his clothing is loosened and a more or less faulty artificial respiration performed. One day a man happened to come along during this battle with death, who had an amyl nitrite pearl in his pocket. On a chance he broke it; some was inhaled and in six minutes the man was walking about, unaided, and reported for work the following day, feeling entirely well. In amyl nitrite an excellent physiological antidote apparently exists. Through dilatation of the peripheral vessels, pressure and distention of the left ventricle is relieved. Blood flows through the dilated coronaries. The high carbon dioxide content of the blood stimulates the respiratory center in the medulla. Several cases have been reported to me regarding the effect of the amyl nitrite. In all the cases so far heard from there has been recovery, and to such an extent that in from five to eight minutes the man has been on his feet, walking about; has walked back to his camp and has been at work the next day without any after-effect. Headache is complained of on regaining consciousness, but is only temporary.

The first point in the line of attack is *instruction* in the proper method of doing Schaefer's artificial respiration. The left arm is generally flexed and placed under left side of head, which is turned toward the right. They make sure the tongue is forward. The danger is that, in excitement, the thoracic cage will be compressed and released too rapidly; so, as they bear downward and inward, with tips of thumbs touching along margin of ribs, they say slowly, "Out goes the bad air"; then on easing the pressure, but without removing the hands, "In comes the good." This will make the respiration just about the required sixteen to eighteen per minute. At the same time a handkerchief or piece of shirt, in which the ampule or "pearl," if not in a fabric container, has been broken (two generally used), is held or placed over mouth and nose. Cold-water affusions are good, if handy. If the sufferer is thin, a coat, rolled up, is placed beneath the lower part of sternum. They must be cautioned, of course, to give nothing by mouth until complete consciousness is regained. A pulmotor is excellent if on hand and in working order. Camphor in oil, and atropin, hypodermically, would undoubtedly be of use, but the beauty of the amyl nitrite is the simplicity of its use in any hands and the almost immediate availability. Time lost in preparing a hypodermic may be fatal. The stimulant is immediately applicable, if the men are properly supplied and instructed. It is a sudden skirmish, quickly finished one way or the other. The construction of a gas mask, or helmet, that will safely destroy the toxicity of this gas or gases, is an important subject for investigation. They are needed about the wells, pipe lines, tanks, stills, and ships.

As to the exact nature of this poisonous gas (or gases), we do not yet know. It is probably some sulphur combination. Communication with Mr. J. G. Detwiler, chief chemist of the Texas Co., elicited the fact that "there are a number of lethal combinations into which sulphur can enter, and it may be possible that some of these exist in these gases." For analysis, he suggested sending ten liters of each gas if not diluted by air, and if diluted, four times as much. This has not yet been accomplished.

It is of interest to note that the industrial treatment of petroleum with sulphuric acid is recognized as an element of distinct danger to the workers (through the evolving of sulphur dioxide).

The Carpathian wells and the wells of the Mexican fields, are "sulphur crudes." Geologically, they occur in the tertiary period. Both affect the central nervous system.

Summary.—In the mystical realm of hydrocarbons we are still at sea. However, it is of greater practical importance to an industry, handling some twenty million barrels of oil a month in the Tampico district alone, to know how to attack this gas, than to know the exact chemical formula. This, however, must be determined and further reports made on the use of amyl nitrite. The gases causing the pulmonary line of symptoms require investigation and a definitely settled method of treatment.

Prophylaxis lies in the proper gas mask, inclosure of gases, and ventilation. The attack on the condition itself demands first aid instruction of all men liable to exposure and a general dispersal of

amyl nitrite, with exact directions, until something better is demonstrated. We are dealing with great depression of the respiratory center and excessive cardiac inhibition (cardio-inhibitory center). Cases of sudden death from chloroform and nitrous oxide gas make us think of the possibility of ventricular fibrillation in these cases. The checking of excessive vagus action¹¹ would make a report on the reaction to atropine very valuable.

The value of our attack lies in efficient and immediate procedure, hence the danger of any reliance on things mechanical, such as pulmotor and hypodermic. There is a Prussian Ministerial Decree, dated January 5, 1909, governing benzine extraction plants in Germany. Most of the large oil companies of this country are working out their lines of safety, with their own special committees. General investigation, with an exchange of reports, should be encouraged. The General Manager of small vision and limited experience and sympathy is a deplorable handicap.

I wish to acknowledge much help in data, obtained from Mr. V. R. Currie, chairman of the Central Committee of Safety of The Texas Co.

19 PARK AVENUE.

INTUSSUSCEPTION IN INFANCY AND CHILDHOOD.

WITH THE REPORT OF A SUCCESSFUL CASE OF RESECTION FOR GANGRENOUS INTUSSUSCEPTION.*

By WALTER M. SILLECK, M.D.,

NEW YORK.

ASSISTANT PROFESSOR OF SURGERY, NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; ASSISTANT VISITING SURGEON, HARLEM HOSPITAL.

(From the Surgical Service of the New York Post-Graduate Hospital.)

THIS subject has been chosen, not with the idea of adding any scientific data to a topic which has already been exhaustively discussed, but rather to bring before you again some of its clinical manifestations, with a plea for the early recognition of the condition and its immediate surgical relief. About 70 per cent. of all cases of intussusception occur during the first year of life, and it is the cause of about 30 to 40 per cent. of all cases of intestinal obstruction. Especially in infancy, intussusception is attended with appalling mortality, some authors giving as high as 73 per cent. Our experience is that the results are directly dependent upon the duration

of the condition prior to operation. The cases operated upon within the first twenty-four hours after the onset, show well over 95 per cent. recoveries in the hands of experienced operators. It is of interest to note the figures which are given by Clubbe of Sydney, Australia. In his first 50 cases, there was a mortality of 50 per cent. In the second 50 cases, the mortality dropped to 25 per cent. The third 50 cases show a mortality of only 8 per cent., and there was not a single death among his following 25 cases. This is, of course, a wonderful tribute to the operator's skill, but I believe that the greatest credit belongs to the practitioner who sees that the case goes to early operation.

The etiology is somewhat obscure, and has been variously attributed by observers to any one, or a combination of, the following conditions; (1) Difference in caliber of large and small intestine; (2) Abnormally loose mesentery; (3) Appendix; (4) Meckel's diverticulum; (5) Ulcers of the intestine due to tuberculosis, syphilis, typhoid fever; (6) Tumors of the intestinal wall; (7) Tumors of the mesentery; (8) Excessive peristalsis; (9) Ileocolitis, etc.

In the vast majority of cases, the beginning invagination is located at or near the ileocecal valve and the degree of telescoping of the intestine may vary from a few inches to several feet. At times the large intestine is invaded throughout its entirety and one easily feels the apex of the intussusceptum by the tip of the examining finger in the rectum. Usually the intussusception is single, but it may be multiple. I have seen a second intussusception in the transverse colon, but never a second one in the small intestine, although they sometimes occur. Recurrences are infrequent, but if taking place within a few days of the primary operation the results seem to be uniformly fatal; however, the cases do well when an interval of months has elapsed. To guard against this distressing condition, I believe that if the patient's condition warrants, the appendix should be removed and, if demonstrable, mesenteric tumors should be excised; likewise the intestine should be resected if a tumor of the same obviously caused the invagination.

The symptoms and course correspond, in general, with any acute internal strangulation, and seldom present any difficulty in diagnosis. Practically always we find a previously healthy and well nourished child and, if an infant, it is usually breast-fed. The child has had apparent, sudden, stabbing abdominal pain with very marked shock and prostration. The onset is usually accompanied by vomiting, with later straining at stool, and possibly some flatus and particles of feces expelled. We, however, practically always find varying amounts of mucus tinged or streaked with blood. After this violent onset, there is a period of apparent well being and the child seems almost normal. This, however, is of short duration and the cramp-like pains return, intermittent and accompanied by rhythmic straining, and larger quantities of bloody mucus are expelled from the rectum.

The presence of a sausage-shaped tumor, appearing not tender and freely movable within the abdominal cavity, makes the diagnosis certain. This tumor may be of any size and be felt anywhere within the abdomen and it is usually tensely elastic

*Read before the Medical Society of the Greater City of New York, January 21, 1921.

in consistency. At times it may be difficult to palpate the tumor; but with a finger in the rectum and the always soft abdomen in children, one should have no difficulty. Clubbe states that in 173 cases, in only two did he fail to palpate the tumor.

Depending upon the completeness of the obstruction, we have in varying degrees, bile, particles of feces, and flatus passed by rectum; in the later stages we find nothing but a mucohemorrhagic fluid. Vomiting is not a constant symptom, and after the onset it may be altogether absent until the later stages of a complete obstruction. When vomiting occurs early and persists one is apt to find an acute strangulation of the blood supply, this leading to an early gangrene. The temperature remains low, even subnormal, but the pulse is greatly accelerated. Later, when gangrene has developed, and the patient becomes toxic from absorption of the necrotic tissue and bowel contents, the picture is the usual one of septic toxemia, and, unless death intervenes, general peritonitis follows. Should this condition be confused with an acute ileocolitis or one of the purpuric diseases, radiography after injection of bismuth solution into the colon, will soon solve the problem.

In a very few instances there has been a spontaneous reduction. Rarely does the intussusception slough off, leaving firm adhesions and a patent intestinal canal. In the very early stages, by careful manipulation, the invagination has been reduced and this also has been accomplished by the use of enemata. However, one must fully realize the danger of these seemingly simple procedures, for the pathology at the site of the lesion predisposes to rupture of the intestine. The above happy and unusual results should never be anticipated, and I positively believe that surgery is not only the safest, but the only certain method of treatment.

The *laparotomy* should be performed as quickly as is consistent with accuracy. I prefer the "compromise" incision, in which the right rectus muscle is split at about the level of the umbilicus. This can be subsequently extended in whichever direction one finds necessary. If possible, deliver the tumor and attempt its reduction by gentle taxis. Begin disinvagination at the apex of the intussusception, and push back to its point of origin. Because of the obstructed blood supply the tissues are very friable, and laceration of the gut and mesentery is liable to happen if attempts are made to "pull it out." If the gut is irreducible or non-viable proceed with resection *immediately*, and do an anastomosis, for now much depends upon the speed of the operator. I close with the usual layer sutures, and the skin with silk worm gut including the rectus fascia, as these wounds do not show the normal rapidity of repair.

The following statistics are from the surgical service at the New York Post-Graduate Hospital, for a period covering the past five years. I wish to thank Dr. R. F. Carter, the resident surgeon, for his kind cooperation in securing these records. There were in all 34 cases, operated upon by six surgeons. The age of those under one year averaged $6\frac{1}{2}$ months. Of those over one year, the average was $2\frac{1}{2}$ years; the oldest child being six. As to the sex, 74 per cent. occurred in males.

It is very interesting to see what the figures show as to the mortality, in relation to the preoperative duration of the condition.

Duration	Number of Cases	Cured	Died
4 days	1	0	1
3 days	1	0	1
2 days	9	0	7
1 day	12	9	3
Less than 24 hours	6	5	1

In four cases no mention was made of duration. Vomiting was present in 77 per cent., and bloody mucus in 97 per cent. of the cases. A mass was felt through the abdominal wall in 16 cases and by rectum in 7 cases. In 5 cases no mass was felt, and in 13 cases no reference was made to this on the chart. As to location, 12 per cent. were limited to the small intestine, the remaining 88 per cent. were at or near the ileocecal valve, involving both large and small intestine. In 71 per cent. of the cases the intussusception was reducible. Resection of the intestine was done in 29 per cent. of the cases, and of these 23 per cent. were gangrenous and 6 per cent. irreducible. Of the resected cases 76 per cent died and 24 per cent recovered; the average amount of gut removed was eight inches. The appendix was removed in 32 per cent. of the cases.

Total cases operated upon, 34; cured, 59 per cent.; died, 41 per cent.

In this series there was one definite recurrence after six months. In one case the gut was perforated while an attempt was being made at reduction. Lobar pneumonia was a complication in one case; one patient died from hemorrhage following an infected wound. One died from a general peritonitis; another from inanition, no surgical cause being found. The remaining cases being profoundly toxic failed to rally.

The following case is of particular interest.

W. L., No. 49,680, age six years. For the past three weeks has had a paroxysmal cough accompanied at times by vomiting; this has improved in the past few days. Twenty-four hours ago he was seized with sudden lancinating pains in the umbilical region, accompanied by prostration. His bowels had moved that day, but an enema was given, and bloody streaked mucus was the only return. Since the onset he has vomited three times. Now the pain has subsided, but returns in rhythmic cramps every three or four hours. Rectal temperature 99° , pulse 128. The child was fairly well developed and did not look very sick. His condition was good. At the left base there were a few crackling rales; heart normal. The abdomen was relaxed and there was no apparent distention. A somewhat solid, gurgling, movable, not tender, mass, about 3 inches long, was felt to the right and above the umbilicus. Rectal examination was negative, excepting there was bloody mucus on the withdrawn finger.

He was immediately taken to the operating room and through a generous right rectus incision the freely movable mass was delivered. Free serosanguineous fluid was found in the peritoneal cavity. The intussusception was found involving only the small intestine; irreducible; very dark in color and apparently non-viable. In all, eighteen inches was resected and an end-to-end anastomosis was done. The wound was closed in layers, silk worm gut in the skin, and a rubber tissue drain inserted. Ether anesthesia was administered, and an infusion of 500 c.c. physiological saline solution was given during the operation. Operative time was twenty-three minutes. On the twenty-first day he left the hospital, and four months later I saw him and found him in excellent condition.

This case serves to illustrate all of the salient points in symptomatology and physical signs of the usual case of intussusception. In addition, operation clearly showed to what extent the gut could be involved after such a short period of time, although the child appeared to be in good physical condition.

The delay of even a few hours in this case, would have unquestionably proved fatal, especially since we know that recovery following resection for gangrenous intussusception is extremely rare.

445 PARK AVENUE.

TREATMENT OF ARTHRITIS BY NONSPECIFIC THEORY.*

BY ISIDOR BETZ, M.D.,

BROOKLYN, N. Y.

ASSOCIATE VISITING PHYSICIAN, GREENPOINT AND BIKUR CHOLIM HOSPITALS.

THE treatment of arthritis by nonspecific proteins is still in the experimental stage, and the clinical reports are relatively few. This report is submitted with a view of confirming its undoubted value in a large percentage of cases.

Our understanding of the way in which animal or man combats disease may be grouped under two theories: (1) specific and (2) nonspecific.

1. The specific theory is based upon the assumption that, when an animal is infected with a given disease, we find in the blood specific antagonistic substances called antibodies; and those substances capable of producing these antibodies are called antigens, *e.g.* Tetanus or type 1 Pneumococcus.

2. The second theory, or nonspecific theory, aims to explain that the cause of all diseases is due to the action of toxins that are fundamentally the same.

There exist in the body nonspecific splitting enzymes, protein in character, that attack invading protein toxins, whether they are bacterial, animal, or vegetable. These nonspecific protein enzymes may be activated by the injection intravenously of various foreign proteins in proper dosage. The most frequent protein used is typhoid vaccine, others being milk, casein, peptone, egg white, etc.

Vaughan has suggested that all proteins, regardless of their origin, have nuclear units which are identical, and this basic unit is toxic. Whipple has identified this as a toxic proteose.

I am indebted to Dr. Lintz for the courtesy of allowing me to use the cases in the medical division. Our report includes fifty cases treated in the past sixteen months that did not yield to any other treatment.

Miller and Lusk report 175 cases of acute, subacute, and chronic arthritis treated by intravenous injection of foreign proteins, and they obtained favorable results in all not complicated by adhesions. The proteins used may be bacterial, animal, or vegetable. In our cases, the gonococcus vaccine was used twice; in all other cases the Board of Health typhoid vaccine was employed diluted in 10 c.c. of physiological salt solution. Although we have had no bad results, Thomas declares he knows of several cases in which the treatment was followed by sudden death. According to Snyder all those cases were in such serious condition at the time the vaccine was administered, that they should not have been considered suitable cases for this treatment.

During the last three years, Kraus, Ludke, Jobling, Snyder, Miller, Lusk, and others have greatly contributed to our knowledge of nonspecific therapy, but no satisfactory explanation for the beneficial

results has as yet been advanced. A plausible explanation is the analogy between the typhoid protein paroxysm and the malarial paroxysm. When we consider the phenomena we are impressed with their similarity. The malarial paroxysm is a protein reaction due to the death of the parent cell, setting free in the blood stream dead malarial proteins and this brings about a group of symptoms almost identical with that induced by the intravenous injection of typhoid protein.

Clinical Phenomena.—(1) Chill. The injection of a foreign protein intravenously is followed in fifteen to thirty minutes by a severe chill, similar to the malarial paroxysm as mentioned above. The entire body shakes, the involuntary muscular contractions probably playing an important part in breaking up small adhesions.

(2). *Temperature.*—The temperature rises in moderate reactions to 103°, in severe reactions to 106° or 107°. Ludke states that as a result of the high temperature the organism is either killed or a firmer union takes place between antibody and antigen. Culver has proven experimentally that it is impossible to infect a patient with gonorrhea during an acute infectious disease. This point is important, since many of our cases of arthritis are due to the gonococci.

Following the chill the patient's body is bathed in an acid perspiration and he complains of headache, abdominal pain, backache, pain in the affected joints, nausea, and at times vomiting.

Blood Changes.—Following the administration of the vaccine there is a mild leucocytosis; during the onset of the chill the white cells rapidly decrease, but after the chill a marked leucocytosis takes place—twenty to seventy-five thousand. At the end of 24 hours, the white cells return to normal.

Complications.—In our series of cases we have not had any untoward effects. The kidneys and heart were carefully watched and no cardiac symptoms were observed.

Results.—In our acute cases most of them cleared up after the first injection. In two cases three injections were required. In all the cases the usual rheumatic remedies were tried in vain and every discoverable focus of infection was removed before the protein was given. In our subacute cases 90 per cent cleared up after one or more injections. In the chronic cases with marked ankylosis a moderate improvement was noted in almost all cases. Even a small improvement in old-standing cases is appreciated by the patients because it gives them a little more ability to use their hands and feet.

Contraindications.—Because of the violent muscular contractions abortions may result. Alcoholic patients, according to Miller and Lusk, are inclined to develop dangerous delirium, and high blood pressure is a contraindication to its use. Before using the vaccine, one should inquire as to previous history of anaphylaxis and observe the following precautions: If more than one injection is necessary, it should be given within six days. Start the treatment with small doses—five to ten million. The average dose is fifty million and the maximum dose 250 million; we have used even larger doses, but the reaction is uncertain and dangerous.

Conclusions.—The consensus of opinion among most of the men using intravenous therapy of for-

*Read before the Clinical Society of the Bikur Cholim Hospital.

eign proteins is that, when the usual drug treatment fails, the intravenous injections often give good results. If recurrence does take place the symptoms are milder in type and relapses occur no oftener than in those patients treated by drug therapy. There is no evidence that intravenous injections have an untoward effect on the heart or kidneys. The treatment is not dangerous if the proper precautions are carried out.

108 HARRISON AVENUE.

BLOODLESS SURGERY IN FLAT FOOT.

BY W. T. CLARK, M.D.,
NEW YORK.

THE difference between flat foot and falling of the arch is one of degree.

Falling of the arch may result from dropping of one or more of the tarsal bones forming the arch. In one hundred consecutive cases treated, the first cuneiform has been found most frequently at fault, followed in frequency by dropping of the cuboid, producing medial or lateral falling of the arch, or both in case the two bones are involved. Next in frequency we find malposition of the scaphoid as secondary to falling of the first cuneiform allowing axial rotation of the scaphoid, carrying the tuberosity upward with a corresponding rotation downward of its narrower lateral side toward the plantar surface of the foot. With one or two bones involved there is partial falling of the arch. When all three bones are involved there is complete falling of the arch or flat foot.

Dropping of the tarsal bones causes more or less pain which sometimes becomes agonizing, as in *metatarsalgia*. In this condition, with dropping of the cuboid bone, the bases of the fourth and fifth metatarsal bones fail to articulate properly with the cuboid and third cuneiform, the tubercle on the base of the fifth metatarsal bone is forced outward and upward becoming more prominent and palpable, and the metatarsal heads are drawn slightly backward out of alignment. This causes impingement upon the external terminal branches of the anterior tibial nerve and the branches of the external plantar nerve, resulting in pain often followed by inflammation which can be detected by a rise in temperature of the adjacent tissues.

Falling of the arch (barring trauma) is a gradual process during which there is more or less constant tension and pressure brought to bear upon some of the nerves, tendons, ligaments, interarticular fibrocartilages, and the muscles. Irritation, followed by inflammation is produced, and this is followed later by the formation of adhesions which sufficiently bind the tarsal bones in an abnormal position to prevent permanent replacement unless sufficient sudden force is exerted to break up the adhesions.

The construction of the arch would naturally prevent rupture of any adhesions by any slow pulling, twisting, or stretching process. It can be accomplished, however, by frequent application of firm but moderate pressure over the plantar surface of the misplaced bone, holding the foot firmly in position and delivering with the palm of the right hand a sharp, jerky blow over the dorsal surface of the metatarsal bones, close to the base.

This causes such a sudden elevation of the bone that (instead of stretching) one or more of the adhesions are instantly snapped and the misplaced bone is suddenly forced upward into its normal position—at least for the time being. This operation must be repeated on alternate days until the adhesions have been entirely broken up. Each operation must be immediately followed by vigorous deep massage of the plantar muscles to dissipate any pain, increase the circulation and nerve supply, develop and strengthen the muscles supporting the arch, and retain the bones in their proper position.

In addition to weakness of the muscles supporting the arch, these cases usually show constant extension of the toes with marked prominence of the extensor tendons. Massage should be applied in a downward direction to the first phalanx, carrying every fifth stroke over the phalangeal extremities, bending the toes gently but firmly downward, producing extreme flexion.

The massage is essential in building up the natural arch support and preventing recurrence. It also assists materially in removing the adhesions by the process of absorption. In cases with tender spots, massage should precede and follow the operation. The pain suffered by most of these patients is relieved by the first few treatments, and complete restoration of the arch is accomplished in 85 per cent. of cases in from six weeks to six months, depending upon the reaction and the severity of the case. This has been the history in one hundred consecutive cases treated by this method.

Taking up the subject of arch supporters, I advise patients who have been wearing them any great length of time to continue wearing them early in the treatment by removing them first two hours, then three hours a day until the supports are gradually dispensed with.

Placed in the shoe, arch supports are worn about fourteen hours a day exerting constant pressure, greatly reducing the blood supply and limiting the action of the plantar muscles, resulting in undernourishment and disuse atrophy. Furthermore, the arch support can give only temporary relief by reducing the strain on the arch and elevating the tarsal bones without breaking up any adhesions or replacing the bones to their normal position. Strapping produces no better results, although it interferes less with the circulation.

Turning in of the ankle and turning out of the heel sometimes occur as secondary to rotation of the scaphoid and unlocking of its articulation with the astragalus, but space does not permit taking up the mechanics of this complication further than to state that its correction depends upon restoration of the arch.

239 WEST 51ST STREET.

Dementia Precox Following Epidemic Encephalitis.—Kahn saw two cases of encephalitis, one lethargic and the other myoclonic, in which one subject developed a hallucinatory psychosis and the other paranoid dementia precox. It is well to state, however, that others speak of false dementia precox as a sequel to this affection. The distinction between true and false is based chiefly on the claim that these dementias recover. Recoverable dementia, as seen in pseudoparesis, pseudodementia precox, and certain postinfectious psychoses, has been classed as an autonomous type of psychosis.—*La Presse Médicale*.

MEDICAL RECORD.

A Weekly Journal of Medicine and Surgery.

New York, May 28, 1921.

THE PATHOGENESIS OF TRAUMATIC HARD EDEMA.

HARD traumatic edema is a trophic disturbance involving the subcutaneous connective tissue and characterized especially by a non-inflammatory tumefaction of this tissue following a trauma, usually without gravity and never involving the skeleton. The tumefaction is hard and painful, causing a marked disability in the neighboring joints. There are often other trophic disturbances present in the skin, hair and nails, the muscles and bones. Its evolution is slowly progressive, its duration often long and out of all proportion with the intensity of the initial trauma. It disappears slowly, complete recovery is frequent, but it is not uncommon to meet with cases which prove obstinate to all treatment. The pathology of this process is not clear and all that is known is that it is characterized by the abundant neoformation of connective tissue fibers occupying the spaces in the subcutaneous connective tissue and dermis. The skin and its adnexa, the muscles and bones are frequently the seat of trophic lesions. The process sometimes resembles markedly certain categories of edema, especially the hysteric when it occurs after a trauma, but it differs from the latter through certain distinct characteristics.

Feilchenfeld was the first to attribute this process to a trophic lesion of the nerves, but we now know that no separate trophic nerve trunks exist. The change must involve all the nerve endings of the area involved but no microscopical study has ever been made. The surgical neuritides commonly follow a trauma, are usually septic and very minute, often collateral nerves of the fingers or toes participating in the serious ascending type of neuritis. But aseptic neuritides certainly exist and reported cases show that simple contusion may result in nervous lesions in certain subjects, and this is probably due to the soil. The tissues of the same individual are not equally resistant, for example, one person with heart disease will derive his asystolia from the liver, another from his kidneys or elsewhere. It is evident that in the subject under consideration the neuroarthritic soil plays an important part and is eminently suited for the development of hard traumatic edema. Any intoxication

likewise strongly reacts on the nervous system, be it an endogenous intoxication—tuberculosis, syphilis, paludism, diabetes—or an exogenous intoxication—alcohol, lead, etc.

The hypothesis of a change in the nerve endings undergoing its evolution in such soils is, we believe, a sufficiently clear explanation for the symptoms observed in hard traumatic edema. The frequent localization of the process on the back of the hand or foot is explained by the fact that the extremities of the limbs are the seat of election for nervous trophic disturbances. The majority of the disturbances of the sensibility are due to changes in the nerve fibers involved by the trauma. The trophic changes in the skin, subcutaneous connective tissue, muscles and bones all readily explain the condition if a neuritis is regarded as the principal factor. The slowness of the evolution of the process, its usual manner of ending, the uselessness of massage and other therapeutic measures also speak in favor of this hypothesis. A neuritis likewise explains the slowness of cicatrization of wounds or incisions made in the edema for therapeutic purposes and the resulting torpid ulcers with a chronic evolution.

In conclusion it may be said that hard traumatic edema is essentially a trophic disturbance probably following a peripheral neuritis whose causative factor is a traumatism, usually slight, occurring in a predisposed soil. In most cases the process is seated on the dorsal aspect of the metatarsus or metacarpus, but it can also be met with in other parts of the body. The symptoms are very variable, probably because under the name of hard traumatic edema, some observers have described hard edemas of a purely hysterical order. This consists especially in a tumefaction, at first elastic, afterwards hard, of the subcutaneous connective tissue, painful on pressure, usually interfering with the functions of the neighboring joints on account of the pain, frequently accompanied by trophic disturbances of the skin, muscles, and bones, and assuming an essentially chronic evolution. Finally, the skeleton never presents fracture or microscopical lesions as the result of the initial traumatism.

THE UREMIA OF NURSINGS.

Two great syndromes may be met with in nurslings that Widál has described in the nephritides, namely, the chloruremic or hydropigenous syndrome and the uremic syndrome. The latter has been misunderstood until recently but nevertheless its importance in nurslings is very great. To detect uremia in babies, it is impossible to use the blood as it cannot be obtained in sufficient amount. On the other hand, it is easy to withdraw enough cerebrospinal fluid for the purpose of estimating the urea and as Widál has shown, the results obtained are comparable. In the normal state the amount of urea in the cerebrospinal fluid is low in nurslings, being about 10 to 35 centigrams, so that when it attains 50 centigrams or more, there is nitrogen retention. It may remain low in

numerous pathological states, but in others it is notably high. Uremia is common in nurslings and Maillet found it in ninety-six babies from one to eighteen months old out of a total of two hundred and ten cases. It is a very serious symptom, since out of these ninety-six cases seventy-eight ended fatally. Uremia appears in various circumstances, but strange to say it has not been detected in the nephritides in infants. During the evolution of acute affections it is met with principally in bronchopneumonia, and acute gastrointestinal processes. In chronic processes it is quite special to athrepsia and this is the only chronic affection in which it has so far been found. The quantitative estimation of urea may be most important for the prognosis. In the acute processes, if the percentage is high from the onset and continues to increase rapidly, death invariably occurs. If the percentage, although high at the onset, returns to normal and remains there, or only increases temporarily from time to time, the prognosis is favorable. On the contrary, should it go up and remain high, death is at hand. When the urea retention is less important but permanent, the prognosis is fatal; the type is athrepsia. It should be said, however, that in nurslings it is not so much the degree of the uremia that is important, but rather its persistency.

Clinically, retention of urea may not give rise to any particular symptom. Such is the case in acute affections in which the accidents of infection overshadow those of intoxication. These may be termed *associated uremias*. In other circumstances it is accompanied by clinical phenomena which should lead to its diagnosis. This is *pure uremia* and presents itself under two aspects. Either it develops during violent accidents in which case there is an acute uremia, or else it is characterized by signs of progressive cachexia in which case there is chronic uremia. Acute uremia is accompanied by gastrointestinal disturbances, loss of weight and above all, nervous phenomena. There is a meningeal type and especially a somnolent form. It creates diagnostic difficulties with tuberculous meningitis and the cytological examination of the cerebrospinal fluid is insufficient to make a diagnostic differentiation between the two morbid processes in some instances, so that it is necessary to have recourse to chemical examination.

Chronic uremia is essentially a cachectic process and realizes Parrot's description of athrepsia. Clinically, it can be described as an athreptic form of uremia of nurslings. The recent notions obtained regarding the uremia of nurslings therefore explain certain points in nursing pathology whose pathogenesis has until recently been obscure. Its part in athrepsia is perhaps the most important. The principal symptoms of this affection are those which characterize the uremic syndrome of adults and it would seem as if athrepsia might be due to the uremia present in these cases. But it is essential to go still further back and to ascertain why this condition arises. It is probable that it does not

depend upon functional renal disturbances, because these appear to be normal, and only minute lesions of the kidney exist, which are in no way comparable to those of the chronic nephritides of adults. On the other hand, nephritides with important renal lesions give rise only to an unimportant ureic retention. Therefore it is probable that complex factors intervene. The study of urea retentions in nurslings not only brings out certain peculiarities of infantile pathology, but it also would seem that it is a new element in this great problem of general physiology and pathology.

REMOVAL OF TATTOO MARKS.

THIS subject, which is much more ancient and voluminous than has been commonly believed, receives a monographic consideration in the *Schweizerische medizinische Wochenschrift* for February 10, 1921, li, 6, at the hands of Cattani. In ancient Rome it appears that slaves and captives were tattooed as a sort of branding to establish ownership or identity, and these subjects were most keen to have the marks removed. Since Scribonius Largus employed cantharides in his prescription for the removal of stigmata it is inferred that blistering answered in some cases of superficial tattooing. Aetius apparently replaced these stigmata by more equivocal scars produced by caustics. In theory the particles must be either discolored or extracted. The substances used, however, are all colloidal and cannot be dissolved. Extraction must almost invariably leave other marks of some kind. As for methods actually in use the author enumerates thirteen. Constant friction seems able in certain cases to make the marks less conspicuous, but this could hold good only in very superficial cases. Vesication is untrustworthy as a method and this applies also to the use of chemical caustics. Electrolysis is impracticable—tedious, painful, not dependable, and apt to cause keloid formation. Carbonic acid snow is now largely used and has given good results in the more superficial cases, but the method is tedious and leaves scarring. Ultraviolet rays, once thought promising, have not made good. The attempt to tattoo a white substance of colloidal nature over deep India ink marks seems logical but has not given satisfaction. One of the more promising resources is the attempt to digest the particles by the use of papain in glycerin and good results have been claimed for it, but others have had only failures.

In addition to the rough use of strong chemical caustics more refined methods have been advocated in which it is aimed to cause a gradual slough. The applications are relatively mild. The technique is complicated and comprises retattooing. Thus, after tannin has been pricked into the entire design, nitrate of silver in stick is rubbed in and then more tannin is added. After two or three weeks the skin sloughs and in several months' time a superficial red scar remains with the original pattern plainly visible. Eventually the scar is less noticeable. The

amount of time and pains, and the risk of infection when strict asepsis is not practised, are drawbacks to the method. The expert use of the galvanocautery is a rapid method of obliterating the pattern, no trace of which is said to persist. The use of the Forest needle with the pole of a high frequency machine is another method of the same class but the author found the pain too great. The slow and painful use of the harpoon for picking out small specks could hardly come into common use. There is a method for removal of very deep tattoo marks which readily suggests itself as sound in theory and this method has given some good results. Incisions are made through the integument and subjacent tissue, the flaps turned back and the ink removed by various instruments. The curette does not answer, and some cutting instrument is required. Among these is an eyelet punch which cuts through the thickness of the skin. The flaps are then restored and scarring should be absent. Another method adapted to superficial marks is shaving off or decorticating the epithelial layers with a razor; it is recommended where there are many follicles and glands. The scar should not be permanent; or if there is danger of scarring, Thiersch grafts may be used. Finally there is always a resort to excision and suture or autoplasty. To sum up, there is no standard method, but a combination of several suitable to the given case—eliminating the tedious and imperfect ones—should hold out much hope of relief.

A CURIOUS ERROR.

THE Bulletin of the Medical Society of the County of New York, announcing the meeting of May 23, contained the following comment on a resolution which had been offered asking Congress to defer action on the amendment to the Volstead act dealing with the medicinal use of malt liquors until after the meeting of the American Medical Association in Boston.

The Comitia Minora sitting as a reference committee has considered this resolution, has conferred with the legal counsel and recommends to the Society that no action be taken thereon for the following reason: The Volstead Act deals with the regulation of intoxicants used for beverage purposes and not with alcohol used for therapeutic purposes, and therefore does not come within the jurisdiction of this Society; should changes in the Act be made to regulate the use of alcohol when used for therapeutic purposes, then only such action should be taken or recommendations made by the Society as will protect the interests of the medical profession in the therapeutic use of alcohol.

Of course both the Volstead Act and the proposed amendment do deal specifically with the medicinal use of alcohol, and it is incomprehensible that the counsel should have made such a statement or that the members of the Comitia should have been willing to accept the responsibility for publishing it.

SPONTANEOUS GANGRENE OF THE SCROTUM.

GANGRENE of the scrotum, when spontaneous, is often most puzzling to the surgeon, for while a micro-organism may sometimes be discovered, the factor

determining its localization often defies detection. Schönbauer reports two cases of this kind from the clinic of von Eiselsberg in Vienna (*Wiener klinische Wochenschrift*, March 3, 1921, xxiv, 9). According to authors there are at least four separate types of genital gangrene in the male, resulting respectively from some general condition, urinary infiltration, direct local insult, or local inflammation. The author's cases belong under the latter class. In both of them there was at first an intense local inflammation, the scrotum in one being of the size of a child's head. The author is entirely silent as to the presence or absence of erysipelas which is so often mentioned as responsible for scrotal gangrene. In the first case the process ended in sloughing. The patient was septic and blood tests showed absence of typhoid fever and syphilis, and of anaerobic infection. Smears from the local secretions were not illuminating although there were many bacteria of a particular unnamed kind—short, thin, Gram-positive bacilli. The gangrenous process involved secondarily the penis and abdominal wall. The second patient died shortly after arrival at the hospital. He presented an advanced degree of gangrene of the genitals. Sloughing had not occurred and the gangrenous areas were ablated. As in the first case, the vaginalis contained a large amount of offensive fluid. Tests after death showed a bacillus in the blood quite distinct from that in the local secretions of the first case. In this second case the author classified them as anaerobes belonging to the *B. oedematiens*. No point could be found to speak for local infection or trauma, and as is so often the case the motivation could not be explained.

OPIATES IN ANXIOUS STATES.

SINCE the passage of Federal and State Drug Laws articles recommending narcotics are not much in evidence among us. This silence does not exist in other countries and in the *Revue médicale de la Suisse romande* for March, 1921, xli, 3, there is an article by Starobinsky on the use of opiates in anxious states. The latter are known to occur in a variety of conditions from neurasthenia and simple melancholia to manic-depressive insanity, dementia precox, paranoia, etc. Whatever the setting, the anxious state yields to some form of opiate—codeine, laudanum, or morphine, in which case it may be necessary to push the dosage. Devaux and Logre in their monograph on anxious states make this recommendation, but it is with the proviso that bromides, valerian, etc., have proved inefficacious. Opium has of course been the sheet anchor for anxious melancholia for many years and as far back as 1874 Voisin was prescribing morphine hypodermics pushed to the limit. This form of treatment naturally created morphine addicts at short notice. Some years later we find that laudanum was recommended, in doses run up if necessary to 200 drops daily. Among those who used laudanum to some extent was Kraepelin. Its action lay in causing the sense of euphoria and of blunting the hyperesthetic moral sense of the melancholic. In prescribing opiates one should endeavor to use a preparation or formula which will offset the tendency to intestinal stasis. The author cites two

cases, in one of which there was suicidal tendency with inveterate insomnia. Attempts to improve the condition by securing sleep failed and as the insomnia was becoming aggravated with acute anxiety, a preparation of opium was given by the mouth. In three days the improvement was striking and the patient was soon discharged cured. The other patient, who believed herself damned for eternity and suffered acute moral pain, yielded much more slowly to the treatment, but was finally discharged completely cured.

TUBERCULOSIS AND DECALCIFICATION.

THAT tuberculosis is to a certain extent a state of decalcification was shown by Ferrier. Pochon discusses the subject in the *Journal de Médecine de Paris* for March 10, 1921, xl, 7. The belief in a lack of lime in the tuberculous organism does not tally very well with the facts, according to Pochon. The recent famine conditions in Europe have been responsible for much tuberculosis and various conditions of the bones of a decalcifying character, but the two classes of patients seem quite distinct. We sometimes see the statement that scrofulo-tuberculous children often present a slight degree of rickets. To convince one that the average tuberculous individual is more decalcified than the average man it would be necessary to show the coexistence of the deformities of late rickets, brittle bones, etc. Pochon gives an account of a highly tuberculous family in which the disease must have spread from person to person. The normal growth rate and the absence of stigmata of rickets, etc., apparently went to show that the lime metabolism had originally been normal. One of the children who was known to have been tuberculous at the age of 11, later became robust, and at the age of 19 was able to play football. During a game of the latter he developed a fracture which could only be understood by the presumption of fragile bones. Radiographs showed absence of callus during the healing process and the entire skeleton showed low lime content, judging by the weak shadows. The fracture failed to unite firmly and after 6 weeks in plaster a second dressing of the same kind was necessary and at present the patient is wearing a brace. There is no pseudarthrosis but union is not firm and the limb cannot be trusted to withstand a strain. At a later period tuberculosis brusquely reappeared in the lungs, as if associated with the poverty in lime of the organism.

THE SOIL IN ENCEPHALITIS EPIDEMICA.

LEFINE writes briefly on this subject in the Neurological number of *La Médecine*, February, 1921, ii, 5. He is in reality considering "infectious" encephalitis so far as his title is concerned, but apparently refers only to the so-called lethargic form, 50 cases of which he has analyzed for predisposition. He regards his finds as marking an advance in our knowledge. Hitherto the time has not been ripe for this study. The first factor isolated is extreme fatigue consequent on some recent physical effort. A condition known as "encephalitis of fatigue" noted before the outbreak of the epidemic may have been the infectious form. Previous influenza was

an inconstant event. The third factor isolated was constitutional nervous fragility manifested at times by emotional instability or perhaps by the presence of an endogenous hereditary factor. There were several migrainous subjects among the victims. Overwork has been mentioned, and to this history must be added insomnia and other results of bombardments during the war. In some of the patients there was a history of sunstroke. The author found in women a connection between the outbreak of the disease and derangements of the genital functions, as the menopause, establishment of the menstrual molimen, and the state of menstruation in general. The evidence of the author is not of much value in the absence of comparison with controls of miscellaneous every-day types of men and women, a large proportion of whom would doubtless have presented the same phenomena as the victims of encephalitis. The author neglects to tabulate or sum up the percentages of these alleged predisposing factors.

News of the Week.

Certified Water on Steamships.—A further step toward insuring travelers on interstate carriers against the evils of polluted drinking water was taken on April 15, when the laws in force in regard to railway trains were extended, with necessary modifications, to steamships on lakes and rivers and between the United States ports and ports of adjacent countries. Henceforth water used on such vessels for drinking or cooking must be obtained on shore from a source approved by the United States Public Health Service, usually acting in co-operation with State health authorities, or must have been treated by a method approved by the service. If not obtained ashore, the water must be treated aboard ship by an approved method. Every tap or other source of water aboard a ship yielding water unsatisfactory for drinking is required to be marked by properly placed signs, approved by the Public Health Service, stating that the water is unfit for drinking purposes. By these regulations it is hoped to prevent outbreaks of typhoid fever and dysentery such as have occurred in the past on several occasions when passengers were supplied with drinking water taken from badly polluted streams.

Typhus Death on Ellis Island.—A five-year-old Yugoslav immigrant died of typhus fever on Ellis Island on May 18. All the aliens who were exposed to the disease were transferred to Hoffman Island for observation and Ellis Island has been placed under quarantine until fumigation has been completed. Representatives of the Public Health Service regard the case as an isolated one.

Oppose Tuberculosis Hospital.—A mass meeting was held in New Orleans at which over 500 persons joined in protest against the erection of a tuberculosis hospital in Southern Park, as proposed by the State Tuberculosis Commission. The opposition came largely from residents of the vicinity in which it is proposed to build the hospital.

Texas Law Regulates Barber Shops.—Under the new law recently passed in Texas no barber will be permitted to work in a shop unless he has a certificate to show that he is free from all communi-

cable disease. He must undergo an examination similar to that now given to food handlers. Not only must barbers be physically examined, but they must keep hot water handy and sterilize every razor, brush, clipper, comb, or other instrument used in a tonsorial operation before it is used again. Most of these regulations are said to be already enforced by city health officials, so that no considerable changes need be made in order to comply with the new law.

American Journal of Tropical Medicine.—We have received the first number of this bimonthly journal published under the auspices of the American Society of Tropical Medicine. The editor is Major H. J. Nichols, M.C., U. S. A., who is assisted by an advisory board composed of most of the men best known in this country for their work in tropical diseases. The publishers are the Williams & Wilkins Company of Baltimore. The first issue contains a number of interesting contributions and its appearance augurs well for the success of this new undertaking. There is no country in the Temperate Zone where a knowledge of tropical pathology is more necessary than in ours, and the Society of Tropical Medicine is to be congratulated on at last possessing an official organ and one that gives such promise of usefulness.

Schick Tests in Cleveland Schools.—The Schick tests which have been carried on in the Sands School will be continued again next fall. Out of 300 letters sent to parents, asking their consent to try the test, 100 favorable replies were received, and of these 100 children 40 were found to be in need of permanent immunization against diphtheria.

Government Hospitals Destroyed by Fire.—Fire caused by a defective flue in the United States Public Health Service Hospital at Palo Alto, Cal., completely destroyed two wards of the hospital, which is built of red wood, in fifteen minutes. The loss is estimated at \$60,000.

Central Nursing Service.—A gift of \$300,000 from Mrs. Jacob Schiff is announced for the purchase of a central administration building for the Visiting Nurse Service under the foundation of the Henry Street Settlement, New York, as a memorial to Jacob H. Schiff. The building purchased is on Fortieth Street, and is to be used as an administrative center, for registrars, statisticians, the making of medical supplies, staff meetings, and classroom purposes, and will serve as a center of public health interest. At the present time there are twenty-two nursing centers in New York which will work under this center. These centers were manned by a staff of 232 nurses during the month of April. This is said to be the first nursing organization in the world that has established a visiting nurse service available for everyone according to their financial ability to pay for professional care.

Madame Curie Receives Many Honors.—The University of Pennsylvania, for the first time in its history, made a special occasion of the granting of an honorary degree, when it conducted special exercises on May 22, for the purpose of conferring upon Madame Curie the degree of Doctor of Laws. At a meeting held in Carnegie Hall, New York, on May 17, under the auspices of the American Association of University Women, a gift of \$2000 was

presented to Madame Curie as a special prize, awarded by the Association to aid scientific research by women. The National Institute of Social Sciences, at its annual dinner at the Waldorf-Astoria, New York, May 19, presented the institute's gold medal to Madame Curie, Vice-President Coolidge making the presentation. The following day Madame Curie went to Washington where President Harding presented her with the gram of radium for use in scientific research, which was the gift of American women. On May 31 a testimonial dinner will be given in her honor at the Hotel Astor by the Poland-America Society.

Medical Schools Consolidate.—At its first session, held in Richmond May 2, the commission on medical education in Virginia adopted a majority report favoring the location of a single state-supported medical school in Richmond, this school to be the medical department of the University of Virginia, with which the Medical College of Virginia is to be consolidated. This resolution will have to be approved by the Legislature before it becomes effective.

Medical College of University of Cincinnati Makes Changes.—At the regular meeting of the Board of Directors of the University on May 3, Dr. A. C. Bachmeyer was appointed professor of hospital administration and Dr. A. C. Geringer was appointed instructor in serology in the Medical College. A donation of \$500 to the Department of Preventive Medicine by Julius Fleischman, former Mayor of Cincinnati, was announced and also the gift of a cafeteria equipment valued at \$5,000 from Mrs. Bettie Fleischman Holmes, widow of Dr. C. R. Holmes.

Colonel Henry Page, U. S. A., has been chosen dean of the Medical College of the University of Cincinnati, to succeed the late Christian R. Holmes.

Dr. Carl Sawyer of Marion, Ohio, was elected president of the Rush Medical College Alumni Association, at its annual banquet held in Columbus on May 4.

Dr. Carlos Chagas, head of the department of health of the Republic of Brazil, was the guest of honor at a dinner at the Waldorf-Astoria on May 20, given by the Rockefeller Foundation.

Dr. John H. Winn has been elected city physician of Columbus, Ga., to succeed Dr. Blandford, resigned.

Charitable Bequests.—By the will of the late Mrs. William L. McLean of Philadelphia, the sum of \$100,000 is bequeathed to the Germantown Hospital and Dispensary as an endowment fund in memory of her parents.

By the will of the late Frederick Eick of Philadelphia, a sum equal to ten per cent. of the residue of an estate amounting to \$176,300, after deduction of a bequest of \$5,000, is bequeathed to the Lankenau Hospital and to St. Joseph's Hospital, each.

By the will of the late Elizabeth Ziegler of Philadelphia the sum of \$5,000 is bequeathed to the Methodist Hospital.

Corrections.—In the article by Dr. Levinson on "A Clinical Study of Tuberculosis in Children," in the issue of May 7, an error occurs in the table on p. 773. In the column under kidney the number should be 1, and not 21 as printed; on p. 775, second column, 22d line, stereopticon should be ster-

eoscopic; on p. 776, second column, under Summary, read: 2.—Of the 141 cases that reacted positively to tuberculin, only 14 or 10 per cent. of the total showed symptoms, etc.

A Public Health Institute.—In view of the unequivocal interest taken by health workers in the recent institute on venereal disease control and social hygiene, as manifested by the large attendance at this institute, conducted by the United States Public Health Service in Washington, D. C., November 22 to December 4, 1920, the Service is proposing to conduct a General Public Health Institute during the fall of 1921. It is planned to offer 25 or 30 courses of instruction in important branches of public health work, which will be given by leading authorities in each particular subject. The institute will make available to persons interested in the various fields of public health endeavor, the most recent contributions of knowledge and experience in their particular field, and will enable them to come into personal contact with leaders recognized to be the highest authorities in the various scientific and practical phases of the work. Further information may be obtained by writing to Surgeon-General Cumming, U. S. P. H. S., Washington, D. C.

Monument to Dr. Robert Battey.—The delegates to the seventy-second annual convention of the Medical Association of Georgia, held in Rome May 5, 1921, unveiled a monument to the late Dr. Robert Battey. The monument was erected by the Seventh District and Floyd County medical societies.

Bloomington Hospital Centennial.—The Bloomington Hospital at White Plains, N. Y., will celebrate its one-hundredth anniversary on June 26, 1921. There will be meetings attended by psychiatrists, neurologists, and insanity experts from many parts of the country. The Bloomington Hospital is one of the oldest institutions for mental and nervous diseases in the United States.

Utica State Hospital to Dedicate Laboratory.—The formal dedication of the George Alder Blumer Research Laboratory will be held on the grounds of the Utica State Hospital on June 4, 1921. There will be a morning session at which scientific papers will be read by well-known psychiatrists and alienists. The new laboratory will be dedicated in the afternoon, when addresses will be made by Dr. Stephen Smith, Dr. Henry M. Hurd, Dr. Edward N. Brush, Dr. Charles W. Pilgrim, Dr. Charles G. Wagner, Professor Walter G. Everett, Hon. Rathbone Gardner, and Hon. P. C. I. DeAngelis.

The Association of American Peroral Endoscopists will hold its annual meeting in Atlantic City, June 1, 1921, under the presidency of Dr. Henry L. Lynah of New York.

Ask Repeal of Statute for Supervised Anesthesia.—The House of Delegates of the Ohio State Medical Association, at its annual meeting, held May 4, 1921, by a vote of 58 to 10, passed resolutions favoring Senate bill 184, which repeals the law permitting nurses to administer anesthetics. This bill was recently passed by the Ohio Senate by a vote of 29 to 6.

The Alumni of the Norwegian Hospital, Brooklyn, celebrated the double centenary meeting of its association on May 11, with a dinner at the

Norwegian Club. The first seven ex-internes of the hospital organized the association in 1898 and since then only two of its members, Dr. Sewell Matheson and Dr. Eugene Charles Lack, have died. Of the 25 members of the association, all but two are in practice in Brooklyn. The dinner was in charge of Drs. C. C. A. Lange, John H. Ohly, and R. E. Coughlin. The officers of the association are: *President*, Dr. John J. Masterson; *Vice-President*, Dr. G. H. V. Hunter; *Secretary and Treasurer*, Dr. Harry A. Fisher. Addresses were made by Dr. Edward D. Ferris, President of the Hospital Staff; Dr. H. Beekman Delatour and Dr. Edward E. Cornwall of the attending staff, and Dr. Adolph Andersen of the interne staff.

Child Welfare at Roubaix.—The American Red Cross and French welfare societies have been conducting a child welfare exhibit at Roubaix, France, under the auspices of the city administration. It comprises exhibits showing the care of babies, demonstrations of hygiene, and lectures on subjects dealing with the rearing of children.

Accommodations Needed for Mental Defectives.—The State Commission for Mental Defectives has made public its annual report in which it asserts that only one-half of the mental defectives in New York State needing institutional care can be accommodated. The commission recommends the construction of additional facilities as soon as the State finances permit. The report estimates that there are about 40,000 mental defectives in the State, adding that not all of these are in need of institutional care. Approval has been given by Governor Miller to a measure permitting the use of the former reformatory at Napanoch for male defective delinquents with criminal tendencies. Similar provision has been made for women at the Bedford Reformatory by the creation of a special division for defective delinquents.

Future Work of Maternity Center Association.—Lack of funds has compelled the Maternity Center Association to withdraw twelve home visiting nurses from those districts in which other public health agencies and hospitals are doing active work, and where, therefore, mothers and babies will not be left totally uncared for. The Association will continue its open doctors' clinics in these districts, making available pre-natal medical supervision for all patients cared for by cooperating agencies. A doctor and a nurse will conduct the clinics one-half day each week. Information as to the location of these clinics may be obtained from the Maternity Center Association headquarters, 370 Seventh Avenue. The Association declares that it has shown that two-thirds of the mothers who die in childbirth can be saved; that one-half the babies that die under one month of age can be saved, and that one-half the still-births can be prevented. Official statistics of the city show for the first time in history a decrease in the mortality rate of infants under one month of age, which, the Association states, proves the tremendous value of this work.

War Hospitals Prepare for Fifty Years' Service. The Bureau of War Risk Insurance is preparing to take care of victims of tuberculosis as a result of war service up to and including the year 1972, and patients suffering from neuropsychoses up to and including the year 1964. These figures are based

on estimates prepared by Dr. C. W. Rucker, chief of the Bureau of War Risk Insurance, which show that the peak of the load in tuberculosis will be reached in 1923, and in neuropsychosis in 1925. The total number of patients who have been received in the hospitals up to March 24 of this year was 116,449, including 30,231 tuberculosis patients; 18,813 neuropsychiatric, and 67,405 general medical and surgical cases. The Bureau of War Risk Insurance is providing treatment for claimants in sixty-one United States Public Health Service Hospitals, five United States Army Hospitals, fourteen United States Navy Hospitals, nine national homes for disabled volunteer soldiers, in St. Elizabeth's Hospital, Washington, and in 1,565 State, county, municipal, and private hospitals under contract. All applicants for relief are examined at these institutions rather than by designated examiners.

The Disabled of Many Nations.—The International Labor office, at Geneva, has accumulated figures which show that eleven nations have 5,500,000 men disabled in the war, not including those of Russia, Turkey, Bulgaria, Australia. Of this number France has 1,500,000; Germany, 1,400,000; Great Britain, 1,170,000; Italy, 570,000; the United States, 200,000; Czechoslovakia, 175,000; Canada, 88,000; Rumania, 84,000, and Belgium, 40,000. Reports sent by the various governments show that only a few of the disabled remain in military hospitals and that the majority of the severely wounded who were properly trained and provided with suitable appliances are capable of earning their livelihood. The difficulty is and always has been to find them an occupation.

Positions for Roentgenologists.—The United States Civil Service Commission announces open competitive examinations for the position of Roentgenologist, at a salary of \$200 to \$250 per month; Associate Roentgenologist, at \$130 to \$180 a month, Assistant Roentgenologist, at \$90 to \$130 a month, and Junior Roentgenologist, at \$70 to \$90 a month. Vacancies requiring similar qualifications will be filled from these examinations. The minimum requirements for eligibility for appointment to these positions are as follows: For the position of roentgenologist applicants must have been graduated from a recognized medical college with the degree of M.D., and have had at least three years' experience in x-ray physics, technology, photography, interpretation, and localization. For the other positions applicants must have completed at least eight grades of common school or equivalent education and have received a certificate of proficiency from an established hospital medical college, or technical institution in x-ray, physics, and technology. Applicants should apply at once for Form 1312, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C. Applications will be received until August 1, 1921.

An Alumni Association of Fordham Hospital has been formed. At its first meeting the following officers were elected: *President*, Dr. Alfred G. Forman; *Vice-President*, Dr. William J. Walker; *Secretary*, Dr. August C. Schwenk; *Treasurer*, John E. Conboy. It was decided to incorporate the Association in the State of New York.

Cooperative Offices for Doctors.—Two five-story

apartment houses in East Fifty-fourth Street are being remodeled for the exclusive use of physicians and surgeons. The title to the property has been taken in the name of the Medical Chambers, Inc. Twenty-four physicians and surgeons have subscribed to the stock in the owner's corporation on the cooperative basis. The building will be ready for occupancy in September.

Obituary Notes.—Dr. Oscaar H. Allis died at Philadelphia on May 16 at the age of 85 years. He was graduated from Jefferson Medical College in the class of 1866. He served as resident physician in the Philadelphia Hospital. He was at one time lecturer on orthopedic surgery in Jefferson Medical College and surgeon to the Jefferson Hospital. He was also surgeon to the Presbyterian Hospital and consulting surgeon to Roosevelt Hospital and the Oncologic Hospital. He was a member of the Philadelphia County Medical Society, the Medical Society of the State of Pennsylvania and a Fellow of the American Medical Association, and a member of the Philadelphia Academy of Surgery.

Dr. LEO J. HINES of Providence, R. I., a graduate of the College of Physicians and Surgeons, Baltimore in 1905, died on May 2, at the age of forty years.

Dr. WALTER DOUGLAS HOSKINS of Indianapolis, a graduate of the Indiana Medical College in 1894, died in a local hospital on April 29, at the age of forty-nine years.

Dr. G. M. STITES of Williamstown, Pa., surgeon of the Susquehanna Coal Company, died in Jefferson Hospital, Phila., on April 29, at the age of sixty years.

Dr. JOHN FRANCIS SNYDER, a graduate of Jefferson Medical College in 1850, died at his home in Virginia, Ill., on May 1, at the age of ninety-one years. He served in the Civil War and later was sent to Congress.

Dr. CHARLES W. DULLES of Philadelphia, a graduate of the University of Pennsylvania Department of Medicine in 1875, died on May 6, at the age of seventy years. He was formerly manager of the University Hospital, and assistant surgeon of the Second Regiment, Pennsylvania National Guard. He was a member of the American Association for the Advancement of Science, the College of Physicians of Philadelphia and the Academy of Surgery.

Dr. JAMES DENNIS V. SHEEHAN, a graduate of the Syracuse University College of Medicine in 1907, died of pneumonia at his home in Syracuse on May 6, at the age of thirty-six years.

Dr. W. W. WALTERS of Greenback, Tenn., a graduate of the Kentucky School of Medicine in 1891, died on May 6, at the age of sixty years.

Dr. E. A. THOMAS of Wyethville, Va., a graduate of the University of Virginia Medical Department in 1891, died suddenly from heart trouble on May 6, at the age of fifty-two years.

Dr. CHARLES ADEN ALLEN of Memphis, Tenn., a graduate of the University of Tennessee Medical Department in 1915, died from tuberculosis on April 26, at the age of forty years. He was a Lieutenant in the Medical Corps of the Army during the recent war.

Dr. J. WEBB CURTIS, a graduate of Harvard Medical School, in 1888, died at his home in Hot

Spring, Ark., on April 6, at the age of sixty-five years.

Dr. BENJAMIN LAIRD, retired, formerly of Vicksburg, Miss., died at his home in Covington, Ky., on May 4, at the age of seventy-four years.

Dr. O. D. RADNEY, a graduate of the Michigan College of Medicine, died in Waco, Texas, on April 26, at the age of fifty-six years.

Dr. FRANK R. LOOMIS of Jefferson, Ohio, a graduate of the Homeopathic Medical College, Cleveland, died from apoplexy on April 24, at the age of sixty-eight years.

Dr. N. B. MORSE of Wyoming, Ill., died of cerebral hemorrhage on April 27, at the age of eighty-three years.

Dr. ARTHUR LEWIS ROOT, a graduate of New York University Medical College in 1883, died at his home in New York City on April 24, at the age of sixty-two years. He was a member of the New York Academy of Medicine, and visiting physician to the Hahnemann and Metropolitan Hospitals.

Dr. GEORGE GLANSVILLE RUSK of Baltimore, Md., a graduate of the University of Maryland School of Medicine in 1867, died on April 13.

Dr. ALFRED BOLEY, formerly a practising physician of Pittsburgh, Pa., died in the Danville (Ill.) branch of the National Soldiers' Home on April 15. He served during the Civil War in the Sixty-third Pennsylvania Volunteer Infantry.

Dr. SAMUEL M. WELLS, a retired practitioner of Orange County, California, died at Virolia, Cal., about April 4.

Dr. ARTHUR BENNETT MORONG of Boston died in a local hospital on May 3 at the age of seventy-two years. He was graduated from Harvard Medical School in 1876, and was formerly professor of physiology in the College of Physicians and Surgeons, Boston. For the past five years he served as ship's surgeon on the lines running to the West Indies. He was a member of the Massachusetts State Medical Society.

Dr. F. H. WIESEWELL, a graduate of the University of Michigan in 1870, died suddenly at his home in Phelps, N. Y., on May 1, at the age of seventy-seven years.

Dr. ROBERT L. JOHNSON, a former practitioner of Alliance, Mo., died on May 5, at the age of eighty-three years.

Dr. FRANCIS L. WATKINS, a graduate of the University of Buffalo in 1891, died at his home in Buffalo on May 13, at the age of fifty-eight years.

Dr. CHARLES W. HALTERMAN of Clarksburg, W. Va., a graduate of the Eclectic Medical College, Cincinnati in 1889, died on May 12, at the age of fifty-three years. He was for several years superintendent of the State Insane Asylum at Weston, a former member of the State Board of Health, and during the late war a captain in the Medical Corps of the Army.

Dr. LEIGH R. GORDON, a graduate of the Louisville Medical College in 1898, died suddenly in Lexington, Ky., on May 8, at the age of fifty-one years.

Dr. HARRY T. INGE of Mobile, Ala., died of hemorrhage from the stomach at his home on May 11 at the age of sixty years. He was a graduate of New York University Medical College in 1883, and one of the founders of the Inge-Bondurant Sanitarium.

Correspondence.

OUR LONDON LETTER.

(From Our Own Correspondent.)

LONDON, May 3, 1921.

Aid from Income Tax for London Hospitals.—In their report just issued the subcommittee appointed by the Executive Committee of King Edward's Hospital Fund to consider the possibility of some form of State assistance to the hospitals by way of allowance in respect of income tax on charitable gifts, suggest a scheme for this purpose which they regard as a practical proposition. It provides that subject to certain limitations, a hospital should be relieved in respect of income tax paid by subscribers and donors in cases where it has received from the contributor a certificate stating that the tax has been paid on the contribution and declaring his desire that relief in respect of that tax should be granted to the hospital. In view of the differences in the "real effective rates of taxes" paid by different individual subscribers, it is suggested that the relief claimable by the hospitals should be based on a flat rate. On the basis of a flat rate of 4s. for every 16s. received the maximum liability of the Government to the London hospitals, based on approximate figures for the year 1920, is £191,000. It must be remembered that, while the total figures shown by the hospital accounts have been taken, certificates would not be obtainable in every case, and that many of the subscriptions would not have been taxed. The subcommittee are of opinion that relief to the hospitals or to a central fund in respect of income tax paid on subscriptions and donations is practicable, that it can be restricted so as not to embarrass the National Exchequer, and that it offers a definite form of financial relief to the hospitals. They believe that the adoption of the scheme would tend to increase subscriptions. They recommend, therefore, that the report be placed before Lord Cave's Committee.

Future of the Hospitals.—Presiding on the evening of April 28 last at the annual meeting of Charing Cross Hospital, Mr. George Verity said when matters were more settled in the industrial and political world a full meeting of the governors would be held under the presidency, he hoped, of Princess Louise, to discuss the threatened altered condition of affairs relating to the working of voluntary hospitals. Chiefly owing to the fight put up by Charing Cross Hospital, the attack on the voluntary system had so far failed. Apart from upsetting the great medical and surgical professions, the Ministry of Health in attempting to interfere with the voluntary hospitals, was very much in line with the old fable of the mountain being in labor and bringing forth a mouse. The present state of uncertainty as to the future was doing an enormous amount of harm to hospitals, and unless it was soon brought to finality the position would be worse than ever. Industrial unrest was having a very detrimental effect upon the income of the hospitals. Although at Charing Cross there had been some loss of income yet, owing to the extraordinary loyalty of subscribers they were able to cover expenditure and

bring forward a balance in what he believed would be one of the leanest years this country had ever experienced. A feature of the year had been the remarkable success of the scheme of voluntary payments. It may be said that Charing Cross occupies a unique position among the London hospitals, nay among the hospitals of Great Britain, in that instead of being in debt it has in hand a balance of more than \$18,000. This result has been achieved by the introduction of organization and business methods in its management. It is not long ago that Charing Cross was in a similar plight to the other hospitals, owed a large amount of money, was running further into debt, and it seemed that there was no escape from the difficulties that beset the hospital. Then Mr. George Verity, a business man who had no experience in the management of hospitals, was induced to try to extricate the affairs of Charing Cross Hospital from the slough into which it had fallen. He consented to make the trial and by the introduction of energetic and original business methods, as by the waving of a magician's wand, the hospital was converted from being almost a Cinderella among such institutions to one of the most prosperous. This example goes to show how much could be done in many of the hospitals if methods of this kind were brought into play.

Surgical Inventions.—It has been stated recently in a daily paper that the London Hospital, in the East End of London, has, by means of the inventions of two members of its staff placed two important additions to the surgeon's art within reach of the profession in all parts of the world. One of these, a new form of sterilized catgut, is the result of over ten years' expert investigation by Mr. H. P. Morley, the chief of the Ligature Department, who has, it is said, produced a catgut that is not only absolutely sterilized, but will "persist" or last for definite periods of ten, twenty, thirty, or forty days in the wound as the surgeon may require, and then become rapidly absorbed after the time specified. The second invention is that of Mr. H. S. Souttar, head of the surgical unit of the hospital, and consists of an eyeless needle. The needle has in place of an eye a minute hole bored longitudinally in the head. An end of the catgut is placed in this and sealed in so that the surgeon can sew with a single thread. Both the inventors have placed their inventions at the disposal of the London Hospital.

The Question of Compulsory Notification for Venereal Diseases.—At a meeting of the London Dermatological Society, held at St. John's Hospital for Diseases of the Skin on April 19 last, a discussion on the resolution, "That the society considers some form of compulsory notification for venereal diseases cases to be necessary," was opened by Dr. W. Knowsley Sibley, the proposer of the resolution. Dr. Sibley said in part, that of the three racial poisons, alcohol, tuberculosis, and syphilis, there is legislation in most countries against alcohol and tuberculosis, but there is still room for legislation in regard to syphilis. Syphilis as a contagious disease, should be taken seriously. In scarlet fever and diphtheria, the infection is of short duration, whereas syphilis, which is not notifiable, may be contagious over a long period.

Dr. Sibley referred to the self-governing colonies and foreign countries in which notification of venereal diseases has proved successful, and of the disadvantages of the voluntary clinic system in vogue in this country. He was of the opinion that if there were some form of even confidential notification a patient would be told he or she must carry out the prescribed medical directions, otherwise such person would be liable to serious penalties. The exact method of procedure following upon notification to the medical officer of health would be a subject for consideration when once the principle had been established. Dr. Dennis Vinrace, who opposed, said that diseases such as scarlet fever and diphtheria were not comparable to syphilis just because of their short duration. The treatment of venereal disease was by far the most important factor to be considered. Prostitutes were the root of the trouble, and until beds could be got to deal with them effectively, venereal disease was bound to continue. No form of compulsory notification could affect this. Dr. Vinrace laid stress on the importance of education of the future generation. He also pointed out the difficulty of diagnosis as an argument against notification. If compulsory notification were brought into force, he believed that the patient would not consult a medical man, but would go to a quack or a chemist. Dr. Maurice G. Hannay agreed with Dr. Vinrace that the question of diagnosis was sometimes extremely difficult. There was also another important question, how long should treatment be continued in any one case infected with venereal disease? In the opinion of Dr. E. F. Bazzard syphilis remains a lifetime. If this is so, it would be a serious thing in the case of compulsory notification. Dr. Charles Banks said that he would support Dr. Sibley's views if it could be so arranged that the notification of venereal disease should be confidential. Dr. A. C. Rebelle felt quite sure that compulsory notification of venereal disease would be of no advantage. No compulsory measures existed in India. The president, Dr. Griffith, said that there seemed to be weighty objections to the compulsory notification of venereal disease. However, the real point was, what would be gained by the compulsory notification of venereal disease, would the disease increase or decrease? The resolution was put to the meeting and was not carried.

Anatomical Study in Great Britain.—A question was asked of the Minister of Health the other day in the House of Commons whether he was aware that there was the greatest difficulty with respect to the proper prosecution of anatomical study in this country, and that in consequence a large number of British medical students were forced to prosecute or complete their studies in foreign hospitals or universities; whether this difficulty was mainly due to the inadequate supply of dead bodies for anatomical purposes, and whether he would consider appointing a select committee to inquire into the matter. Sir A. Mond, in reply, said although it was the case that owing to the difficulty in obtaining subjects, English students have occasionally gone abroad to seek facilities for the study of anatomy in foreign schools, this state of affairs has now been reme-

died by the action taken by my predecessor. There is still a shortage in the case of certain provincial medical schools, but this is being remedied.

Hospital Amalgamation.—At a special meeting of the governors of Alexandra Hospital for Cripple Children the other day, a resolution was passed authorizing the board to enter into negotiations with St. Bartholomew's Hospital with a view to amalgamation.

Influenza in France.—Reports from France on the influenza situation received on April 29 last, state that in some districts there was an extension of the influenza epidemic among soldiers. There were 300 in hospitals in Bordeaux, 240 at Montpelier, and 30 at Troyes, where 8 have died. At Versailles 84 soldiers entered the hospital in one day, and the number being treated there was 250. Three have died. In consequence of the outbreak the cavalry maneuvers on the Chevreuloup Plain have been postponed. More deaths have occurred at Dijon, Grenoble, Perigueux, and Tarbes. A statement issued by the War Ministry recently shows that the evolution of the malady has varied according to the district. In most of the garrisons it is of a benign character, and its spread is due to recruits coming from places where it was prevalent. The French army medical men express themselves as confident that the situation will improve with the return of more favorable weather.

OUR LETTER FROM GENEVA.

(From Our Own Correspondent.)

GENEVA, May 1, 1921.

Serodiagnosis of Syphilis.—Some recent work on the comparative value of certain reactions of serodiagnosis of syphilis, carried out by Dr. Hubert Jaeger at the medical clinic of the University and which has not as yet been reported in the medical press, is not devoid of interest. Wassermann's reaction was found positive in 6 per cent. of nonsyphilitic patients, especially in nephritis and pulmonary tuberculosis. In primary syphilis it was positive in 100 per cent. of the cases; in secondary syphilis it was only once negative, and in this case Bauer's and Bruck's reactions were positive. In tertiary syphilis and parasyphilis, Wassermann was positive in 40 per cent. of the cases, but all the patients had been given specific treatment.

Bauer's reaction was positive in 8 per cent. of nonsyphilitic patients, this being the case especially in nephritis and pulmonary tuberculosis. In primary syphilis this reaction was positive in 100 per cent. of the cases, and nearly 100 per cent. in secondary lues. It was found to be a little more sensitive than Wassermann in tertiary syphilis and parasyphilis. Its concordance with the Wassermann existed in 90 per cent. of the total number of cases examined and in 95 per cent. of the positive cases.

Bruck's No. I reaction (nitric acid) was positive in 14 per cent. of nonsyphilitic patients, especially in pulmonary tuberculosis, and slight plus in 29 per cent. of non-syphilitics. In the various phases of syphilis Jaeger only found it distinctly positive in 8 per cent. of the cases and preferably so in the tertiary phase. Its concord-

ance with Wassermann existed in 61 per cent. of the total number of cases examined, but in only 12 per cent. of the positive cases. Its concordance with Bruck's No. II existed in 56.5 per cent. of all cases examined, but only in 8 per cent. of the cases in which Bruck II was positive. Its concordance with Bruck No. III existed in 56.5 per cent. of all cases examined and in 15 per cent. of the cases where Bruck No. III was positive. Bruck's No. II (alcohol) was positive in 25 per cent. nonsyphilitic patients, this being frequent in the nephritides; in the various phases of syphilis it was positive in 54 per cent., preferably in advanced lues. Its concordance with Wassermann existed in 58 per cent. of the totality of cases examined and in 55 per cent. of the positive cases. Its concordance with Bruck No. III existed in 87 per cent. of all cases and in 80 per cent. in which Bruck No. III was positive. Bruck's No. III (lactic acid) was positive in 29 per cent. nonsyphilitic patients in very varied diseases. In the various phases of syphilis it was positive in 59 per cent. of the cases, preferably in the advanced stages of lues. Its concordance with Wassermann existed in 55 per cent. of all the cases examined and in 51 per cent. of the positive cases.

Chemistry of the Gastric Symptoms.—Some results obtained by Dr. Nimhin, working at the medical clinic, on the chemism of the stomach are interesting. In four cases of gastric cancer, offering the usual symptoms, three went to autopsy and were confirmed as to the clinical diagnosis. There were two other cases of suspected carcinoma; suspected only, because in one the disease dated back several years and in the second some of the more important signs of the disease were wanting. Nevertheless, in all six cases the analysis of the gastric juice showed absence of free HCl and a diminished total acidity. The specific gravity varied in these cases from 1010 to 1026. Consequently, these results approach those obtained by Meunier. As an explanation of this relatively low specific gravity, Nimhin supposes that it resulted from the gastric retention, which was very considerable in two cases, having, respectively, a sp. gr. of 1012 and 1010. According to Léon Meunier, the amount of glucose is always above 10 grams in the gastric juice of hypohydrochloria, and Nimhin found from 16 to 26 grams in four of the cases, while in the remaining two, in which gastric retention was considerable, they gave, respectively, 7 grams 10 centigrams and 10 grams. Two cases examined were clinically instances of hyperhydrochloria, but analysis of the gastric juice failed to show more than a slight increase of the total acidity in one and a diminution of the acids in the other. The sp. gr. 1025-1026 approached that of hypohydrochloria gastric juice and was, therefore, more in accord with the chemism than with the clinical aspects of the cases, and this applies to one case in relation to the glucose (25 grams), but in the second patient there was only 10 grams with a very moderate gastric retention.

There were four cases of gastritis, atonia, and gastroparesis examined. In all four free HCl was absent, total acidity was below normal, and in

three there was some retention, while in the fourth patient it was very manifest. The high sp. gr. of 1025 and 1026 in three was only 1019 in the fourth case. Dosage of the sugar content of the gastric juice in the four cases gave, respectively, 17 grams 1 centigram, 16 grams, 33 grams, and in the last case 25 grams, regardless of the low sp. gr.; namely, 1019, and a gastric contents of 389 c.c.

The last group of cases comprised nervous patients complaining of dyspeptic disturbances, in all seven patients. In them the gastric chemism was quite variable, which is not astonishing. However, speaking in a general way, the free HCl was rather decreased than otherwise, excepting in one case where it could be regarded as normal. The total acidity oscillated between 0.80 and 3.20 and in only one patient was there any notable retention. As to the sp. gr. it varied between 1,019 and 1,027. In one case it was only 1,009, in spite of a manifest hypohydrochloria, while in another case it was 1,010 with increased acidity. Finally, the amount of glucose in all seven cases was over 10 grams per 1,000 c.c. The parallelism between the sp. gr. and the quantity of sugar is the same in this group as in the first (gastric cancer), with the exception of one case only. Nimhin, therefore, believes from his findings, that the specific gravity of the gastric juice obtained one hour after Ewald's test meal oscillates between 1,019 and 1,034 in hypohydrochloria and in hyperhydrochloria it is 1,010 with little variation. Glucose is less than 10 grams per liter in hyperhydrochloria and varies from 12 to 33 grams in hypoacid gastric juice. However, when there is a certain degree of retention (above 350 c.c.), in spite of a very marked decrease of the acids, there may be a low specific gravity (1,010-1,012) with small amounts of sugar just as is found in the chemism of hyperhydrochloria.

2. **Hereditary Edema.**—Charles F. Painter and Harold C. Bean report three cases of this condition, sometimes designated as Milroy's disease. No theories concerning it have been advanced except hereditary. One should not be satisfied with that viewpoint until every other cause has been exhausted. Indeed, heredity cannot be the entire cause, for there must be some weakness or tendency upon which heredity plays its rôle. The nearest approach one can make in this line is upon the endocrine gland theory. In these days of rock-bottom research, glands are beginning to play a part and, with no other better reason to be discovered, the glandular theory can be applied to these cases.

4. **The Spirochetal Value of Disodium Ethyl Arsenate (Monarsone).**—Henry J. Nichols conducted a series of experiments to determine the actual effect of this drug on *Spirocheta pallida* and experimental lesions. From these observations he concluded that disodium ethyl arsenate, or monarsone, tested on rabbits infected with syphilis shows no spirochetal power. The tissues are fatally poisoned as soon as or before the spirochetes are affected. For its practical use in syphilis there is no such germicidal basis as exists in case of the arsenamine group.

7. **The Effect of Small Doses of Atropine on the Heart Rate.**—Hugh McGuigan holds that small doses of atropine, if they influence the heart rate, only slow it. This slowing is produced by an action on the vagus center in the medulla. There may also be some stimulation of the vagus endings. Larger doses of atropine, 0.001 gm. (1/60 grain), still cause slowing, with a tendency to irregularity. This is the point at which the vagus endings begin to be paralyzed. If the dose is still further increased, 0.002 gm. (1/30 grain), the primary slowing of the heart rate may be so transient that it escapes notice. If the object in giving atropine is to paralyze the vagus endings and release the heart (presumably also to relax the smaller bronchioles), at least 1/60 grain, hypodermically, is necessary. In urgent cases 1/30 grain should be given.

9. **The Route and Rate of Absorption of Subcutaneously Injected Serum in Relation to the Occurrence of Sudden Death After Injection of Antitoxic Horse Serum.**—Julian H. Lewis was prompted to make the investigation upon which this contribution is based because of the apparent discrepancy between fact and theory in the matter involved. Most of the recorded cases, it is pointed out, of sudden death with symptoms of anaphylaxis which have resulted from injection of foreign proteins in man have followed subcutaneous injections. Furthermore, in most cases, the onset of the symptoms, and often the fatal termination, occurred a very few minutes after the injection. However, it should be impossible to produce death by subcutaneous injection of serum in ordinary amounts, because the normal rate of absorption from the subcutaneous tissues is very slow, and it is known from experimental anaphylaxis that in order to produce acute anaphylactic death the antigen must get into the circulation rapidly. From his investigation the following conclusions are drawn: The complement fixation test can be used to detect extremely small amounts of one serum in the presence of larger amounts of another. The absorption of serum from the subcutaneous tissues is very slow. The main route of absorption from the subcutaneous tissues is through the lymphatics. The rate of absorption of horse serum injected subcutaneously is apparently too slow to explain the cases of sudden anaphylactic death which have occasionally followed the administration of antitoxic serums in man. Certain procedures, such as massage of the site of injection, and the injecting of large volumes under high pressure, can hasten the appearance in the circulation of horse serum injected subcutaneously. Because of the suddenness with which it appears, and because of the analogy to the occurrence of fat emboli after the subcutaneous injection of oily substances, acute anaphylactic death in man following subcutaneous injections of horse serum is probably due to an accidental intravenous injection of the serum. The need of care to exclude as far as possible the injury of a subcutaneous blood vessel

during subcutaneous injection of horse serum is indicated.

1. **Loose Bodies in Joints.**—A. G. Timbrell Fisher, in this Hunterian Lecture, gives a study of loose bodies composed of cartilage, or of cartilage and bone, occurring in joints, with special reference to their pathology and etiology. Foreign bodies in joints do not come within the scope of this paper. The loose bodies under consideration may be classified into three groups: Group I.—Loose bodies occurring in connection with some more or less general pathological process affecting the joint, such as: (a) osteoarthritis; (b) tabes; (c) tuberculous disease accompanied by necrotic caries; (d) acute arthritis, due to infection. Group II.—Loose bodies occurring in joints that are otherwise apparently normal: (a) bodies having the microscopic, and frequently the macroscopic, appearances of detached portions of the articular surfaces; (b) bodies derived from interarticular fibrocartilages; (c) bodies formed from detached epiphyses not forming portions of an articulating area. Group III.—Synovial chondromata, laminated and nonlaminated: (a) single; (b) multiple; (c) diffuse. In the present stage of knowledge it is impossible to dogmatize upon the etiology of the more important loose bodies of Group I—that is, the osteophytes, since it is bound up with the larger question of the etiology of osteoarthritis. Similarly, the etiology of Group III, the synovial chondromata, is bound up with the larger question of the etiology of tumors. Although it is probable that the cartilage cells in the synovial villi from which they originate are derived from the primitive cartilaginous bar which, in the developing embryo, becomes cleft to form the knee-joint, the periphery remains to become the capsule and synovial membrane. Trauma, however, may undoubtedly be a contributory factor. The writer deals chiefly with the etiology of the type of loose body derived from the articular surface (Group II), all of which are considered of traumatic origin. The classical symptoms of a loose body, sudden attacks of severe pain, often followed by swelling or momentary locking, are due either to the body becoming suddenly and momentarily nipped between the articular surfaces or between the capsule and the joint ends. The symptoms vary with the type of loose body. The treatment of the cases of traumatic loose bodies and of the synovial chondromata is, in most instances, removal. In the case of the pathological loose bodies in osteoarthritis, an operation is usually indicated in young or middle-aged people when troublesome locking occurs and when the joint is not seriously disorganized. Any operation for the removal of loose bodies should be preceded by an x-ray examination taken in two planes, from which one may learn how and where to open the joint. An x-ray is helpful only when the loose body contains bone.

3. **The Etiology of Rickets.**—D. Noël Paton and A. Watson, from this experimental investigation, formulate the following conclusions: (1) In young dogs, under ordinary laboratory conditions, a liberal allowance of milk fat up to even 14 grams per kilo of body weight neither prevents the onset of rickets nor cures it when it has developed. (2) Pups kept largely in the open air may escape the development of rickets on an intake of less than 1 gram of milk fat per kilo of body weight. (3) With scrupulous care as to cleanliness it is possible to rear pups free of rickets in the laboratory on an intake of only about 0.5 gram of milk fat per kilo of body weight, along with bread, provided that the diet affords an adequate supply of energy. (4) The energy value of the diet, however supplied, quite apart from the presence of any hypothetical anti-rachitic factor in milk fat, would seem to play a part in controlling the development of rickets, but that it is only a contributory part is shown by the development of rickets in pups with a high energy intake when they are confined in the laboratory without scrupulous care as to cleanliness. (5) Milk fat may be reduced to about 0.3 gram per kilo of body weight, if its place is taken by an equal amount of lard, without the onset of rickets. (6) The results of these observations do not support the conclusion of the accessory food factors committee of the Medical Research Council that rickets is a deficiency disease due to lack of an anti-rachitic factor associated with milk fat.

2. **Symptomless Hematuria: A Plea for Early Investigation.**—James B. Macalpine emphasizes the points that hematuria is frequently the only symptoms of a growth of the urinary tract; that following this expression of its presence it may retire into absolute quiescence for a long period, during which it is probably increasing in size and advancing toward malignancy; that when it reasserts itself, whether by a second hemorrhage, or by pain, or dysuria, or the presence of a lump, it may have passed beyond the operable stage, and that, if the growth should prove to be of the upper urinary tract, the only time at which a diagnosis of the anatomical site can be made is during the period of actual bleeding. The moral is obvious, but often missed: Hematuria is not a symptom to be treated *per se*. It is a red danger sign, urgently demanding an accurate diagnosis—first as regards its anatomical point of origin, and secondly as regards its pathological cause. It is an easy matter to put a man suffering from hematuria to bed, apply cold, and administer certain reputed hemostatics. Such a course may be rewarded by a cessation of the hematuria, and the medical attendant will have the gratitude of his patient, but surely, on contemplation, must have the mortification of realizing that he has done him a great disservice. Much better had it even been if he had kept him in active life, and rather sought to perpetuate the hemorrhage than to allay it, till such time as a cystoscopic examination could be arranged, and the source of the hemorrhage accurately located. Once the hemorrhage is stopped the opportunity has passed, possibly for a long period and unless some gross swelling of one kidney can be palpated, or the patient is persuaded to submit to a cystoscopy, which may reveal some causative bladder condition, the golden opportunity has gone by and may not recur till much valuable time has been lost. However, the doctor is frequently not responsible for the delay, for patients often cannot be brought to realize the importance of the condition, so long as it is unaccompanied by pain or discomfort. Nevertheless, emphasis is laid on the responsibility of the medical attendant, since the importance of an early cystoscopic examination has not been adequately brought home in the past. Had symptomless hema-

turia been as common as the acute appendix, it would have gone through the same phases that the acute abdomen experienced fifteen years ago, and would now be invariably submitted to immediate cystoscopy, just as the acute abdomen is invariably submitted to immediate laparotomy.

1. Nasal Sinus Infection as a Causal Factor in Appendicitis.—P. Watson-Williams, reviewing and analyzing the cases of definite infective nasal sinusitis occurring in his private practice during two years, found that there were 90 cases, and that no less than 14 had undergone appendicectomy; that is over 15.5 per cent. Cases in which symptoms of appendicitis were reported were excluded unless appendectomy was performed. In several of the 14 cases, which the writer tabulates, the length of time between the appendix operation and the recognition of the sinus affection was too long to justify the assumption of a causal interdependence. It is certain, however, that a chronic nasal sinusitis often has a very prolonged latent period of infectivity without any symptoms sufficiently definite to arouse suspicion until, with some intercurrent cause for exacerbation, the mild latent infection develops signs and clinical manifestations so pronounced that the sinusitis is supposed to have arisen *de novo*. Furthermore, it is unlikely that acute suppurative sinusitis will cause appendicitis, inasmuch as it is then an acute focal infection, while the gastrointestinal tract will be more prone to succumb to a chronic or recurring mass infection from a constant swallowing of organisms. If the element of chronicity is a point to remember as regards nasal sinusitis, it is equally so as regards appendicitis, and it seems probable that an acute appendicitis is usually only an acute exacerbation of a previous latent infection with a relatively long prodromal period. Hence, in collecting statistics, it is impossible to draw a line and assume that, because the appendix infection culminated long before the chronic sinus infection declared itself by severe clinical manifestations, their interdependence must be ignored. It is considered noteworthy that in the list of 14 cases of appendicectomy two were also operated on for duodenal ulcers, while of those not included in the appendix group, there were also among the series of 90 patients two cases of gastric ulcer (one short-circuited), and several others with a history of colitis and gastric catarrh. The incidence of nasal sinus infection in patients suffering from appendicitis could be more accurately determined by exploring the maxillary antra and the sphenoidal sinuses of every patient subjected to appendectomy. At any rate it seems right and proper to make careful inquiry for symptoms and signs of nasal sinus infection in patients suffering from appendicitis and gastric ulcer.

7. Further Observations of the Pigment Changes Following Removal of the Epithelial Hypophysis and the Pineal Gland in the Frog Tadpole. Wayne E. Atwell.
3. Physiological Hyperthyroidism.—Harlow Brooks points out a condition under which symptoms of thyroid

disturbance appear, symptoms mistakenly regarded as indicating serious and permanent disease. The interesting fact to be deduced from these cases is that treatment should not be directed to prevent or circumvent these efforts on the part of the gland, but that, while in many instances it may be necessary to direct or guide nature's efforts, it is unwise to attempt measures, and particularly radical measures, which inflict changes or limitations of a permanent character on the gland in question. Under the category in question are cited numerous hypothetical as well as actual cases among boys and young men and girls and young women. Doubtless there is no more familiar example of physiological hyperthyroidism than is frequently seen in the developing youth. In fact, many of the characteristics which are regarded as a part of youth itself are but probable evidences of thyroid activity. The condition is brought about by an abnormally great demand on the thyroid as the result of developmental growth associated with too much emotional output. When these factors are either diminished within normal limits or directed into other channels, automatically the overaction of the gland, together with other secondary factors that may be associated with it, drops toward the normal; but if the urge is too long continued, or if fixed habits of demand and response be established, the condition will develop either into Graves' disease or will take on a neurasthenic phase likely to ruin the life of the individual. It appears, then, to be but a normal response to an exaggerated or abnormal demand, with the final establishment of a tissue habit. These instances of thyroid activity do not call for surgical or other radical treatment. On the contrary, when these are enforced serious permanent harm is likely to result—either a subsequent hyperthyroidism or an alteration or holding in abeyance of natural and normal tendencies which, when compared to mediocrity, in their full efflorescence lie very close to genius. A failure to comprehend and correctly manage these cases leads to Graves' disease, to neurasthenia or eventual nervous and physical inadequacy.

5. The Special Service Rendered to the Human Organism by the Sympathetic and Parasympathetic Systems, Including Both Nerves and Glands of Internal Secretion.—F. M. Pottenger summarizes this discussion as follows: 1. Physiological action in smooth musculature and secreting glands is controlled by the vegetative nerves and the glands of internal secretion, and is influenced by stimuli either of physical or psychological origin. 2. The vegetative nerves are divided into two systems, the sympathetic and parasympathetic. The glands of internal secretion may in a measure likewise be divided into those which act with the sympathetics and those which act with the parasympathetics. 3. The sympathetic nerves and the sympathetotropic glands of internal secretion aid in the defense of the organism against such conditions as enemies from without, infection, pain, anger, injury, heat, cold, asphyxia, and shock. The parasympathetic nerves and parasympathetotropic glands of internal secretion provide the body with an appetite and the secretions—salivary, gastric, biliary, pancreatic, and intestinal—for the digestion of food, and motor power to the gastrointestinal tube, for mixing the food with the secretions and propelling it onward, and for expelling the refuse from the body.

4. Address—Brooklyn Cardiological Society. Wm. J. Cruikshank.
3. Cerebral Abscess with Masked Symptoms.—R. E. Coughlin reports this case, in which the patient was in a condition of pregnancy, with all the symptoms of kidney disease, including convulsions, vomiting, headache, anemia, a leucocytosis of 16,000, high-tension pulse. Linked with all these symptoms were all the classical symptoms of meningitis, excepting the condition of a negative spinal fluid. The patient died after all apparent means had been employed to locate her

disease, and the necropsy showed the diseased condition in the left hemisphere of the brain, where there had never been the slightest sign to indicate the location of abscess. Operative evacuation of the abscess is the only treatment that can be considered, yet it is impossible to operate when the symptoms bear no relation to the location of the abscess, as in this case.

Wiener klinische Wochenschrift.

February 10, 1921, xxxiv, 6.

Softening of the Spine.—Eisler and Hass have described a new affection of the vertebrae which they term a form of osteomalacia localized in the spine. Clinically it is expressed chiefly by pain and kyphosis, and objectively by radiographic alterations. It is occurring in massed incidence, and hence is of more than merely scientific interest. Both sexes are attacked, and mostly during middle life. The pains are felt throughout the spine and worst in the sacral region. They are much aggravated on rising from the sitting posture. As the condition progresses there is complaint of prostration, trembling of the legs, inability to work, and insomnia. The sitting posture is avoided, but even when recumbent the pain may be severe. The patient in time becomes bedridden, the psychic is altered, and there is the impression of a very sick man or woman. Objectively there is moderate kyphosis involving the entire spine with a soft pillow-like swelling over the sacrum. The long bones are quite normal. The tender areas over the spine vary from time to time, although predominating about the sacrum. None of the other bones is sensitive. Passive motion of the spine does not cause pain, but active exertion, especially stooping, is attended with severe suffering. The first suggestion is of a spondylitis with the addition of neuralgia, and next in order metastases of malignant tumor. Differential diagnosis is made incidentally by the x-ray, for the affections mentioned are more or less localized. In advanced cases there is plainly a poverty of lime. The cure is comprised of phosphorus (no particulars are given), orthopedic support, and the quartz lamp for the pains. The most important question as to the dependence of this condition on underfeeding is not even alluded to, although we know that the famine conditions have caused a form of osteomalacia in Poland.

Wiener klinische Wochenschrift.

February 17, 1921, xxxiv, 7.

Action of Curare in Tetanus.—Schoenbauer of the First Surgical Clinic, University of Vienna, calls attention to the shortcomings of antitoxin in the treatment of tetanus as contrasted with its preventive efficiency. The reason for this dissimilarity is apparent, because the serum when given for prophylaxis can get to the blood mass before the toxin of the disease and thus exert its protective action on the nervous tissues. The author, upholding the efficacy of prophylactic injections, states that of 1300 open wounds treated in an accident station the immediate use of 20 units of antitoxin was followed by a solitary case of lockjaw. This case went from bad to worse, despite all treatment. In casting about for a new resource the author recalled that during the war curare was tested, although apparently with negative result. It occurred to him to give this old drug a trial. An opportunity was offered when an accident victim was brought in with the full picture of tetanus, 10 days after having received a severe lacerated contused wound of the head. The wound, which apparently had not been dressed, was first treated and antitoxin given locally and by subcutaneous and intravenous injection. There was no response and the symptoms progressed. Chloral was then exhibited, and incidentally a small dose of curare, repeated until 6 mgm. had been injected. This quantity produced overaction (asphyxia), and the dose was limited to 5 mgm. daily with 45 grains of chloral. Under this treatment the spasms ceased for some hours daily, to reappear sooner or later with varying severity. The patient recovered after having taken 63 mgm. of curare in 14 days. In using this drug everything depends on the quality, and the preparation used

should be tested on a warm-blooded animal before using, as was done in the author's case.

New Formation of Cells in the Adult Organism.—Professor Corning of Basle discusses this important subject which lies at the base of regenerative processes, tumor growth, etc. He begins with the original cell multiplication which follows impregnation and initiates development. This, however, takes no account of parthenogenic phenomena, a subject naturally of great moment. The experiments of Bataillon and J. Loeb have shown that the spermatozoid is not essential to development. The nature of the irritation which brings about formative development is obscure. Apparently it is necessary only for some irritant to start cell division, after which organ growth and form look out for themselves. Thus living organisms can unaided cause the formation of plant galls. Nucleus and cell division go ahead with slight intermissions, but this process is seldom long interrupted. The mass of protoplasm concerned is not a measure of growth. The completely developed organ contains a constant cell count, and this is of course true of the individual as a whole. Thus at one stage of development a certain larva contains 450 cells, indicating a fixed limit to cell division. Formation of over large structures means that a normal inhibiting force has defaulted or has been prematurely exerted. According to circumstances, then, we see giant and dwarf formations in which conceivably the number of cells is larger or smaller than normal. Such developments are seen alike in impregnated and unimpregnated ova. Differences in growth rate may be seen in epithelial as compared with connective tissue, in which the evolution of one tissue may influence the development of the other, and the author discriminates between interstitial and appositional growth. In epithelial tissue which is constantly cast off and regenerated mitotic figures are common in the deeper layers. In the supporting tissues mitoses do not occur in bone cells, and in cartilage cells are of doubtful occurrence, and in loose or formed connective tissue occur but rarely; although the cells retain their ability to subdivide. Mitoses are also rare in some of the epithelial cells, as those of the liver and kidneys. In brief as far as we can generalize there is a definite relationship between frequency of mitoses and ability to regenerate. Mitoses in these parenchymatous organs when present at all are seen only in growing animals. In adults the blood is seen to have full powers of regeneration and this is true of the cells of the bone marrow from which the blood corpuscles are formed. The author discusses direct and indirect cell division. In a few organs direct subdivision goes on throughout life, in others the number of cells in the structures reaches its limit soon after birth, while in still others the number is completed at the end of the embryonal period. In the first class are the cells which form the spermatozooids and blood corpuscles, in the second the parenchymatous organs, the loose connective tissue and cartilages and in the third muscle and nerve substance. Nail and hair growth are typical regenerative processes with typical mitoses in the stratum germinativum.

Mumps and Meningitis.—The fear of orchitis as a complication of mumps doubtless is partly responsible for the indifference toward meningitis, the possibility of which seldom occurs to the practitioner. Yet not a few cases of this complication are on record. Feer of Zürich reported a case in 1919 in a boy of 8 years. In such cases one is first apt to think of tuberculous meningitis. No bacillary finds are mentioned. German literature is poor in this subject. French cases seem less infrequent. Bourdillon of Geneva saw a case in 1915 in a girl of 10. Like Feer's case, it ended in recovery (secondary meningitis in the course of acute infectious diseases is said to be relatively benign). There were no bacillary finds. This complication is evidently due to the unknown specific cause of mumps and not to the lighting up of a meningococcus or streptococcus infection.—*Revue médicale de la Suisse romande.*

Book Reviews.

THE PRINCIPLES OF THERAPEUTICS. By OLIVER T. OSBORNE, M.A., M.D., Professor of Therapeutics, Department of Medicine, Yale University. Philadelphia and London: W. B. Saunders Company, 1921.

THIS is an interesting book to read here and there, and there is a lot of sound information in it. It is not, however, adapted for use as a textbook, either of materia medica or of therapeutics. For the young graduate, however, it is a capital guide, for it will serve to refresh his memory as to the action of certain drugs, and may also give him some new ideas of real practical worth. As a finished production the book would have been improved had it ended on p. 775, for the following hundred pages have no place in a work on therapeutics. There is a section of 20 pages dealing with the "treatment of simple disturbances of the surface of the body," ending with leucorrhœa! This is good so far as it goes, but why stop with dermatology? The treatment of internal disorders is certainly as important. A chapter on "practical advice to young physicians," ending with a section on life extension, is good, but the material is not usually regarded as a division of therapeutics. And the book ends with the Code of Ethics! Why not the Gospel according to St. Luke? The writer of that treatise was a physician and it is cram full of ethics—even better than the ethics of the A. M. A.; and then it contains some therapeutics, too, as well as case histories, which the revered Code does not, so it would really be a more fitting appendix to a work on the healing side of medicine.

DISEASES OF THE EAR. By PHILIP D. KERRISON, M.D., Aural Surgeon in the Willard Parker Hospital for Infectious Diseases, Junior Aural Surgeon in the Manhattan Eye and Ear Hospital, Fellow of the American College of Surgeons, etc. Second edition. Revised and enlarged. Philadelphia and London: J. B. Lippincott Company.

THE first edition of this work, which appeared some eight years ago, met with well-deserved favor with both otologists and general practitioners. The present edition contains all the good features of the first, such as the excellent illustrations of the successive stages of the several operations; indeed, all the illustrations are good and, when taken with the clear descriptive style of the author, facilitate greatly an understanding of the operations. In this edition two chapters have been added—one on the pointing tests of vestibular and cerebellar disease and another on deafness occasioned in war by air concussion and other traumatic incident to war.

GYNECOLOGY. By BROOKE M. ANSPACH, M.D., Associate in Gynecology, University of Pennsylvania. With an Introduction by JOHN G. CLARK, M. D. 526 illustrations. Philadelphia and London: J. B. Lippincott Company. 1921.

ANOTHER gynecology in the medical and surgical literary field to smile or to fight its way into popularity among medical students and that almost extinct species—the general practitioner. This work has been aided on its way by an introduction from Dr. John G. Clark, who, in the conclusion of his introductory note, extends a "cordial commendation to a book that has had the well-balanced authorship of a specialist who has devoted a number of years to faithful work as an investigator and as a teacher, and to the practice of gynecology and abdominal surgery in their broadest and best sense." Truly, the author of this book may be proud of his achievement, for he has covered his field in a clean-cut, masterly fashion, and in addition has summoned to his assistance the best literature and opinions on his specialty. The arrangement of the subject matter is so logical, simple, and direct that this effort adds much to the pleasure of study from this work. The necessary anatomy, physiology, and pathology are given and of course operative procedures as well as prophylactic and hygienic care of patients. One of the most unique chapters in the book is that pertaining to backache, that bugbear among women. That in itself shows how such knowledge has broadened and deepened in the past fifteen

years. Exercise, with the exercises plainly illustrated, is well discussed and the subject of correct support from correct type of dress, such as corsets, etc., is most sensibly given to the reader so that there can be no doubt as to what the author means, and certainly no haziness as to his methods of treatment. The book is decidedly refreshing and tends to spur on interest in this specialty. Why do not more surgeons, who have practically the medical control of so many women's lives, study the big preventive field in physiology as well as the remedial side of pathological states? This author has on no narrow-visioned surgical spectacles, but straight-seeing, almost far-visioned medical eyeglasses. The illustrations are superb and an excellent bibliography follows each chapter. One might wish that at times there had not been shown such a surgical method of statement of facts, which tends to give them almost too much crispness, so that, here and there, they seem to be knocked at one as a hammer might be. However, when the priceless moments in a practitioner's life are considered in which there is time for reading and study, perhaps this habit of abruptness on the part of the author may be for a definite, studied result.

THE PRINCIPLES OF ANTE-NATAL AND POST-NATAL CHILD PHYSIOLOGY. By W. M. FELDMAN, M.B., B.S. (Lond.), Assistant Physician to and Lecturer on Child Physiology at the Infants' Hospital. With six plates and 129 illustrations. New York and London: Longmans, Green & Co. 1920.

THIS book is the first of its kind in any language. It is the outcome of a series of lectures delivered at the Infants' Hospital. The book is designed to appeal to the student of physiology, to the pediatricist, and to all conversant with the study of children. The pioneers on the subject of antenatal and postnatal life, Leonard Hill and J. W. Ballantyne, lent valuable aid to Dr. Feldman in the preparation of this volume so that it has an authoritative scientific standing. The subject is thoroughly discussed from the earliest stages of life, namely, the germinal cells until puberty, every step in the development being considered. The functions of each system in the body of the fetus are carefully described. Of great interest is the chapter on the fetal secretions and internal secretions. The physiology of pregnancy and of birth and the changes that take place in the mother and infant are accurately explained. The postnatal development of the child is really a volume in itself, every angle of anatomy, physiology, and metabolism, as well as the development of the systems of special sense organs, being especially commendable.

PRINCIPLES OF BIOCHEMISTRY. For Students of Medicine, Agriculture, and Related Sciences. By T. BRAILSFORD ROBERTSON, Ph.D., D.Sc., Professor of Physiology and Biochemistry in the University of Adelaide, South Australia. Philadelphia and New York: Lea & Febiger, 1920.

THE author presents the subject of biochemistry in close relationship to physiology and has constructed a textbook primarily for the use of medical students and students intending to specialize in biochemistry and physiology. But his purpose has been to make it useful also to the student of agriculture or general biology and to the industrial chemist. He has been highly successful in accomplishing his purpose. He has produced a book of some 600 pages which touches illuminatingly, if at times briefly, upon practically all of the phases of that very complex division of chemical knowledge which we have come to know as biochemistry. Its production has demanded more than superficial knowledge of the allied subjects of physics, physical chemistry, biology, bacteriology, immunology, and mathematics, and the reader is continually impressed with the author's broadness of vision and information. But perhaps the most striking feature of the work is the evidence in nearly every paragraph of the author's philosophical attitude and active scientific imagination. These contribute to make the book fascinating and stimulating reading, wholly apart from its value as a text in the subject. His final chapter, "The Outlook," is a masterpiece of scientific prevision. This is a book that everyone should read.

Society Reports.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

One Hundred and Fiftenth Annual Meeting, Held in Brooklyn, May 3, 4, and 5, 1921.

(Continued from page 891.)

SECTION ON MEDICINE.

Wednesday, May 4—Second Day.

DR. RICHARD G. RUSSELL OF BUFFALO IN THE CHAIR.

Intestinal Tuberculosis.—Dr. LAWRENCE BROWN and Dr. H. L. SAMPSON of Saranac Lake presented this communication which was illustrated by charts and lantern slides. They stated that the records of the New York State Department of Health showed that of 19,612 persons dying of tuberculosis in this State 17,235 had died of pulmonary tuberculosis. Three and one-half per cent. were certified as having some abdominal complication. The figures obtained at autopsy, however, seemed to show a much higher percentage of intestinal involvement. In a study of 89 consecutive cases at Trudeau to ascertain what percentage had intestinal tuberculosis, they found about 6 per cent. The present status of the diagnosis of intestinal tuberculosis was comparable to that of the diagnosis of pulmonary tuberculosis twenty-five years ago. The symptoms presented by intestinal tuberculosis were diarrhea, or constipation, or diarrhea and constipation alternating, pain, tender points in the abdomen, or rigidity. The finding of tubercle bacilli in the feces was of little value as a large percentage of cases of pulmonary tuberculosis showed tubercle bacilli in the feces as well as in the sputum. Constipation, digestive disturbance and failure of the pulmonary condition to improve were further evidences of the presence of intestinal tuberculosis. An irregular temperature with subnormal fluctuations with marked nervousness were also suggestive of tuberculous peritonitis. The bismuth meal and the x-ray were valuable aids in the diagnosis of intestinal tuberculosis. Failure of the cecum to fill, with segmentation of some of the coils of the small intestine and general hypermotility were indications of intestinal tuberculosis. Colitis occurring in a tuberculous patient was nearly always a tuberculous colitis. Operation was not indicated in advanced cases of tuberculous peritonitis though it might be resorted to in early localized cases. Heliotherapy applied by means of the mercury quartz lamp should be tried in all cases; in some instances the result of this form of therapy was striking. During the past three years they had studied almost 800 cases of tuberculosis roentgenographically, and had found that when, after giving the opaque meal, the barium was found in the ileum and transverse colon, with none in the cecum it was almost pathognomonic of intestinal tuberculosis. In some cases, apparently normal at first, this defect would be evident after twenty-four hours. In some advanced cases the barium reached the ileum in six hours, but there would be nothing in the ileum, the ascending or the transverse colon. In the earlier part of their work the patient ate nothing from the time the barium meal was taken until the radiographic observations were completed, but they now asked the patients to bring a bite to eat after the sixth or seventh hour as this sometimes hastened the passage of the barium out of the small bowel into the large bowel so that a defect could be visualized.

Dr. LEON T. LE WALT of New York emphasized the diagnostic possibilities of the x-ray, and cited the fact that in gastric ulcer and carcinoma of the stomach the x-ray enabled them to make correct diagnoses in over 90 per cent. of the cases, as proved by operation or autopsy. Dr. Le Walt cited a case of tuberculosis of the cecum and ascending colon in which there were no pulmonary lesions so far as the x-ray or symptomatology of the case was concerned. He believed it to be one of primary tuberculosis of the colon and cecum. By Dr. Brown's technique he had been able to make the diagnosis. Dr. Downes had operated upon the pa-

tient and now, two or three years after the operation, there was no recurrence of the symptoms. Dr. Le Walt asked Dr. Brown what his feeling was with reference to the diagnosis of tuberculosis of the small intestine. He stated that they had made the diagnosis of tuberculosis of the small intestine on the x-ray evidence of dilatation and segmentation of the small intestine as proved at operation. He also asked Dr. Brown whether he had had any experience with tuberculosis of the stomach. He stated that they had one case at Bellevue recorded as tuberculosis of the stomach though there was some question as to whether it might not be a syphilitic lesion instead of a tuberculous ulcer.

Dr. J. W. DRAPER said he had had the privilege of operating on one of the cases that Dr. Brown had described, in whom there was an extensive involvement of the ileum, ascending colon, and appendix. In this case the patient's condition was such that he was only able to remove the appendix at the operation. It was the opinion of the staff that the patient would not recover unless a secondary operation was performed. The patient refused further operative interference, and, much to their astonishment, had made a most astonishing recovery. Dr. Draper said he had always been interested in the pathology and etiology of infections of the right side of the colon and had studied the pathological findings in 150 cases in which specimens were removed at operation. This series did not embrace more than about 3 per cent. of tuberculosis. An interesting question in connection with this work was why tuberculosis, streptococcus and colon bacillus infections occurred in this region almost to the exclusion of every other part of the intestinal canal. This had been explained by certain embryological features leading to conditions which tended to lower resistance in this location. He thought we should all be grateful to Dr. Brown for having shown that too great rapidity in the emptying of the intestinal tract after the giving of an opaque meal might be just as significant as too great delay.

Dr. MARY DUNNING-ROSE of New York said she thought we all recognized when dealing with a chest case of tuberculosis that we were not dealing merely with a local condition, but with a general disease. Probably many of the bad results in surgery were due to the fact that they removed only the local manifestation of a general disease and the operation only served to still further lower the resistance of the patient while the disease still existed. She said she had been waiting to hear someone mention tuberculin in the treatment of abdominal tuberculosis. She cited the case of an Italian woman who had tuberculous peritonitis and was subjected to an exploratory laparotomy; extensive involvement was found and the patient was sent home to die. The woman sent for another physician, who treated her with tuberculin. She had seen the woman three years after the operation when she was apparently in good health. That had decided her to study the action of tuberculin and to learn to use it, which was something one could not learn from books. If one could not administer tuberculin without causing a febrile reaction it was time that person stopped using it, because if one obtained high febrile reactions after the administration of tuberculin he was going to lose the case. One should start with the fifth or sixth dilution and be extremely careful of the technique. It was important to be sure that the syringe was thoroughly washed out or one might be giving a much higher dosage than he thought he was giving. The proper use of tuberculin would save some of these cases of tuberculous peritonitis that otherwise would be lost.

Dr. GEORGE REESE SATTERLEE of New York said he had had the pleasure of witnessing some of the work done at Saranac. The work should not be misunderstood. It was not always possible to make the diagnosis of intestinal tuberculosis with the x-ray, but this work would lead to further study along these lines. He had made a study of colitis cases, and in tuberculosis of the cecum it was much more difficult to fill the cecum than in ulcerative colitis or in the presence of a specific lesion. Dr. Satterlee emphasized the importance of not giving a meal at night before making an x-ray examination of the colon. He asked Dr. Brown whether he

had come to any conclusion as to the route by which infection took place, whether it was by way of the lymphatics or whether by direct infection from the interior of the intestine. He thought tuberculosis of the intestines was comparatively rare. In over 1000 cases they had seldom made a diagnosis of a tuberculous intestinal lesion. It was important to exercise great care in making a diagnosis from the morphology alone.

Dr. BROWN, in closing the discussion, said that at Saranac they saw very few cases of tuberculous except the pulmonary lesions and so they rarely saw tuberculous peritonitis in cases other than those of pulmonary tuberculosis. He had never seen a case of primary tuberculosis of the stomach. The source of the infection in tuberculous peritonitis he thought was from the sputum through the intestinal wall. It seemed that parts subjected to the greatest strain were infected first. They had found about 85 per cent. of intestinal tuberculosis at or around the ileocecal valve. In their series they had had no primary intestinal lesion at all.

The Importance of the Medical History in the Diagnosis of Chronic Gastrointestinal Disease.—Dr. WILLIAM GOLDIE of Toronto, Canada, presented this communication. He stated that the rapid accumulation of new facts, theories, and tests made it difficult to retain a sense of proportion and to guard against the present tendency to lay hold upon some pathognomonic sign or seek some short cut to a diagnosis. Textbooks showed an exasperating vagueness in their symptomatology of chronic intestinal conditions, and such an indefiniteness that often an interchange of titles would not add greatly to the confusion. New facts had given rise to the conception that the majority of symptoms of chronic gastrointestinal disease were dependent upon defects in the activity of the muscular elements of the intestinal tract. This conception has so far been in keeping with clinical findings, and its adoption had led to the sorting out of certain symptom complexes having a definite meaning. It had reasonably accounted for the activities and interaction of the various portions of the intestinal tract, and provided a satisfactory explanation for the absence of certain symptoms where expected in such pathological conditions as gastric and duodenal ulcer, and for the presence of symptoms supposed to indicate ulcer when no ulcer existed. The application of such a conception necessitated at least a working knowledge of how the nucleus worked, when they worked, when they relaxed, what were the common causes that altered the normal action, and the time of relaxation, action and rest. There was a periodicity of relaxation, action, and rest dependent upon the delivery of the stomach, since there was an intimate relation between the stomach and the parts beyond the stomach. This was borne out by the findings of the physiologist, the radiologist, the surgeon and the clinician, and led one to believe that over 90 per cent. of patients complaining of gastric symptoms had no organic disease of the stomach. It was further borne out by the revelations of the embryologist as to the development and innervation of the tract and its relationship to the higher nervous centers and the various segments or somites of the body. How should we apply our new knowledge? Each portion of the day must be searched with a clear idea of the normal state of the muscular elements of all parts in each of these periods—the period after waking, the period of desire for and reception of food, the period of active delivery, the period of lessening delivery, and the period of rest and hunger. Then there should be an inquiry as to what provoked or exaggerated symptoms, what was the influence of worry or nervous tension, what the frequency of bowel evacuation, what the discomfort before, during, and after meals, whether there was a sense of ease or satisfaction after meals, what was the character of the stools, etc. After eliciting all the complaints and their relation to the daily cycle one was able to determine whether the complaint had its origin in the defective action of the musculature or whether they were due to some other affection such as irritation of the peritoneum or some mechanical defect. Other questions to be asked were whether all the attacks had been the same as the present one; how long was the longest; how short the shortest; how long were the intervals between attacks? Were there symptoms

in the so-called interval? Did any slight or severe illness precede the first attack? The past history was then taken up seeking for evidence that pointed to recurring infection, local irritation, inflammation, etc. Cases were cited showing the need of giving attention to the daily cycle as a whole. Questions should cover the health in infancy, not merely whether the subject had the diseases of infancy, but what kind of a recovery he made from those infections, information in regard to run-down periods, growing pains, frequency of sore throat, bronchitis, recurring vomiting with or without headaches, pleurisy, anemia, ability to keep up with other children. Of 127 cases of chronic disease of the gall-bladder proved by operation or by undoubted x-ray evidence showing the presence of a stone, 74, or 58 per cent. gave a history of recurring attacks in childhood or adolescence; 31, or 24.4 per cent. gave a history of a definite attack of cholecystitis in young and adult life; 22, or 17.3 per cent. were unable to recall bilious attacks or any recognizable attack of cholecystitis later in life. In contrast to these, 500 histories of all conditions other than chronic disease of the gall-bladder, 37, or 7.4 per cent. gave a history of bilious attacks occurring in childhood and adolescence.

Interpretation of Gastrointestinal Signs and Symptoms.—Dr. FRED WHITNEY ROLPH of Toronto, Canada, read this paper, in which he attempted to bring together some of the more striking phenomena of digestive derangements and to link them up with the causes by which they were produced. (1) There was the desire for food. In an atonic stomach we fail to obtain the tone which initiates the desire to eat and after entrance of food into the stomach the gastric wall contracts so little that there is but slight satisfaction obtained from a meal. On the other hand, there may be an overcontracted stomach, especially in the pyloric region, where the desire for food was intense but a small portion satisfied. It was in these latter cases that food excited sufficient contraction to produce pain, nausea and vomiting. The writer did not believe that the degree of acidity had any direct effect on the desire for food; an excellent and even an excessive appetite was not inconsistent with gastric achylia. (2) Belching and regurgitation were not of clinical importance and were due to the cardia being well relaxed during eating and for a short time afterwards. The most important factor in etiology was an increase in the intragastric pressure (or hypersensitivity to normal pressure) which imparted to the patient a feeling of fullness in the epigastrium and came from muscular contraction of the stomach wall due in part to swallowed air or gas from fermentation. The relief afforded by opening of the cardia led these patients to make swallowing efforts which might develop into the habit of air swallowing. The tonic contracture of the gastric musculature was not seldom a reflex effect, most commonly from the gallbladder. (3) Nausea and vomiting might be due to many reflex causes. (4) Hemorrhage was by no means always the result of ulceration; an even commoner cause than ulcer was rupture of veins in the esophagus or in the pyloric region. (5) Pain and tenderness. In discussing pain and tenderness the writer reviewed morphology of the intestinal tube and its accessory organs and of the nerve supply requisite to an understanding of pain and tenderness. Irritation of the mucous membranes had been pretty well discarded as a cause of abdominal pain. It was now recognized that the important etiological factor lay in the distention of the unstriated muscle in the walls of the viscus. This might be due to organic obstruction, but a more frequent cause was an excessive contraction or spasm of the visceral wall, the result in turn of a reflex from some other part of the body. While pain was primarily a viscerosensory reflex referred to the skin and underlying tissue which had nervous relationship to the organ involved, he thought we must admit that at times there was direct pain on pressure over the diseased organ. After making a survey of painful sensations associated with individual abdominal lesions, he stated that the so-called symptoms of duodenal ulcer were in reality the symptoms of duodenal spasm. Ulcer of the duodenum itself did not give rise to symptoms except by increase of local spasm, obstruction or peritoneal irritation. Ulcer of the stomach had a wider origin than that of the

duodenum, it also was bound up in reflex spasm, and distension. Many ulcers appeared to be associated with and were probably secondary to duodenal spasm reflexes from a diseased gallbladder. Gastroenterostomy relieved hunger pain by providing a safety valve and preventing distension, but unless the origin of the vagus irritability was removed did not cure the ulcer in the duodenum. It was in cholecystitis with or without stones that one found the most extensive and varied reflex effects and findings. There was one sign never found absent in gallbladder disease, that was spasm over the left half of the transverse colon with tenderness over it just to the left of the middle line. Also there was a tender area just below and to the right of the umbilicus. Colonic spasm was the probable cause of a mucous colitis which was seldom found unless gallbladder disease was also present. Another reflex one saw occasionally was esophageal spasm, evidently of vagal origin. In this connection an important consideration arose in that the gallbladder was supplied by the left vagus which had little effect upon the heart rate, so that bradycardia did not occur as a reflex from that organ, though it might do so from the presence of bile in the blood stream.

Dr. A. SORESI said we had gone through the period when the pathologist made the diagnosis and were now in the period when the radiologist made the diagnosis, he contended that it was the privilege of the clinician to make the diagnosis. He thought the history was not the first issue. One should first have all the facts with reference to the physical signs and symptoms; then the x-ray examination and all other kinds of tests, then the history, and finally the conclusion. Dr. Soresi took exception to the statement that gastroenterostomy relieved the symptoms of gastric ulcer. He did not think gastroenterostomy cured gastric ulcer and it cured very few duodenal ulcers.

Dr. L. P. VAN WINKLE of Amityville emphasized the importance of the history; though it might be unreliable in a few instances, in the majority of cases it was all important. We had the pathological laboratory, gastric analyses and x-ray findings, but when all was said and done, he believed they should do as they had done in the past, go over the case in the light of the history, taking into consideration the other findings simply as aid to the physical examination and history.

Dr. ELIZA M. MOSHER of Brooklyn pointed out that by auscultation and percussion it was perfectly easy to outline the abdominal contents just as one did in the heart or lungs. She had found that by laying a paper over the abdominal wall it acted as a sounding board by which the borders of the stomach, transverse colon, cecum could be located. One could find what the pull of the transverse colon was upon the stomach and the gallbladder and where the thin places were in the walls of the intestines. By giving a glass of water one could follow the contents of the stomach through the entire intestinal tract. After taking a glass of water, if the patient flexed the knees and took a long breath and then emptied the lungs, as the diaphragm was raised there would be a contraction of the recti muscles over the stomach, and the contents of the stomach would be moved on into the pylorus. She had had patients employ this procedure after meals and had found the outline of the stomach very materially improved after a short period.

Dr. GOLDIE, in closing the discussion, further emphasized the importance of history. While all the laboratory, x-ray, and other special examinations were of value it was only by working out the symptom complex in a systematic way that one was able to come to a diagnosis easily and rapidly. Students should be trained to depend more upon the history and clinical findings and less upon the laboratory and x-ray findings.

Further Developments in Pneumoperitoneal X-Ray Diagnosis.—Lantern Slides.—Drs. WILLIAM H. STEWART and ARTHUR STEIN of New York made this presentation, in which they stated that artificial inflation of the peritoneal cavity with gas or mixtures of gas had proved itself to be perfectly safe in skilled hands. In 175 examinations made in this way there had been no untoward result. The method had shown itself superior to any other in the diagnosis of intraabdominal lesions. It was the only method by which one could

obtain information in reference to adhesions and to conditions localized beneath the diaphragm. It was a great aid in the diagnosis of conditions of the liver and gallbladder. They could by this means demonstrate a single stone in the gallbladder or innumerable small stones. Retroperitoneal growths could also be outlined. It was an aid in certain gynecological conditions, though they had not thus far been able to outline the fetus in the uterus. The method was contraindicated in the presence of acute appendicitis and peritonitis and in patients with valvular disease of the heart, as well as in certain types of elderly alcoholic patients. The accessories required in preparing the patient for examination were a tank containing the gas to be used, to which was attached by means of a rubber tube a rubber bag. This helped to control the pressure of the gas. The other outlet of the tank was attached by a rubber tube to the lumbar puncture needle used in making the injection. A quarter of a grain of morphine was given fifteen minutes before the examination to dull the pain in the abdomen caused by the distension. The needle properly sterilized was inserted from one to three inches below the umbilicus in the median line, avoiding any old operative scars. The quantity of gas injected depended upon the degree of relaxation of the abdominal wall. If it was much relaxed as much as four liters might be required; in young subjects with firm abdominal walls two liters might be sufficient. After the inflation the needle was withdrawn and adhesive plaster applied over the puncture. The procedure must be carried out under modern aseptic technique. Carbon dioxide would be absorbed in twenty minutes after its injection. If the abdominal distension was desired for a longer period two parts of carbon dioxide and one of oxygen might be used and if an examination of the entire abdomen was to be made oxygen should be used, as it was not so readily absorbed. After the examination the needle could be reinserted and the abdomen deflated. Slides illustrated the detail of the technique and the various conditions that could be diagnosed in this way. Even enlarged peritoneal glands could be seen, it was possible to differentiate between tumors of the kidney and those of the liver and of the spleen; the arterial system of the abdomen could be demonstrated.

(To be continued.)

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, Held March 23, 1921.

THE PRESIDENT, DR. GEORGE MORRIS PIERSOL, IN THE CHAIR.

Modern Methods in the Diagnosis of Renal Disorders.—

Dr. ROSS V. PATTERSON read this paper, in which he said that the study of a patient suspected to be the subject of renal disease involved, for the most part, the use of methods of comparatively recent development. The general conception of renal disease has veered from an anatomical to a functional basis. Until comparatively recently, for want of a better plan of classification, the clinical endeavor was to group forms of renal disease into several anatomical types, according to post mortem findings. The clinical investigation consisted in ordinary urinary examinations, often yielding findings interpreted as indicating renal disease when none existed, or, perhaps, quite as often failed to reveal such disease when present and well advanced. Toxic symptoms, edema, arterial sclerosis and hypertension, anemia and cardiac hypertrophy were associated findings upon which considerable diagnostic dependence was placed. In the chronic forms only well advanced cases were recognized, and most of them were beyond amelioration. The more recent tendency to develop a functional estimate had made for earlier recognition and given more confidence and exactitude to both diagnosis and treatment. The importance of a functional conception of renal disease became apparent when it was realized that anatomical lesions were incorrigible; a rational plan of treatment by a regulation of the diet was one in which the demand made upon the kidney was lessened to within its decreased functional capacity. Unless the

nature and degree of functional impairment were ascertained, there was no definite basis upon which to base either prognosis or treatment. Diagnosis included the recognition of both the nature and the degree of a disorder. Anatomical lesions had an importance in proportion to the functional impairment which they occasioned. Normal kidneys were capable of exercising a functional capacity several times greater than was necessitated by the demands made upon them under ordinary circumstances. Their accommodation limits enabled them to meet, without overstrain, unusual, exceptional and variable conditions, in which waste products, in varying amounts, gained access to the blood; despite the constantly changing burden of waste products, the composition content percentages remained fixed, or varied only within narrow limits. One of the early evidences of kidney disease might be found in a retention of the chlorides in the blood and tissues with a diminished elimination in the urine. The normal urinary chloride content was 1.8 per cent.; the amount might be reduced to 0.5 per cent. or less in disease. With impairment of renal function and consequent blood retention, the total nonprotein nitrogen might reach 100 or 200 mg., or more, per 100 c.c. of blood. Blood urea was chiefly responsible for the increase of the urea nitrogen, often constituting 70 to 90 per cent. of the total. Uric acid occasioned the greatest difficulty in elimination; creatinine, the least; urea occupied an intermediate place. Uric acid concentration was an early evidence of renal failure; creatinine concentration occurred only as a late manifestation, and was an evidence of advanced disease. A value exceeding 5 mg. per 100 c.c. of blood had usually terminated fatally; it might reach 15 to 20 mg. A marked increase in the total nonprotein nitrogen might be a herald of uremia, although uremia might occur with a low retention, indicating that some other element was the essential factor in its production. The vicarious function of other organs might be a factor in preventing nitrogen concentration with failing kidneys. The skin, liver, stomach, intestines, and even the bronchial tubes, might excrete urea, and perhaps other nitrogenous substances as well. A patient with severe nephritis and oliguria expectorated a daily average of 1500 c.c. of sputum, containing over 2 per cent. of urea. With an increase in urine, the amount of sputum and the percentage of urea rapidly diminished. It was only comparatively recently, however, that functional tests had been so simplified and extended that they could be used with ease and accuracy by any practitioner. Many important aspects of kidney function were revealed by the simplest tests requiring only careful observation and intelligent interpretation. The normal kidney excreted urine that varies in concentration at different times in the twenty-four hour period. There was a reaction to both food and fluid stimuli, so that the molecular concentration of the blood remained within fixed normal limits. The kidneys showed considerable flexibility in their ability to meet these varied demands, and this flexibility might be measured with some degree of accuracy in various ways. A careful determination of the specific gravity and quantity of both day and night urine yielded important data. A knowledge of these two factors made possible an estimate of the total amount of solids excreted. The amount of urea excreted could easily be determined by the use of the ureometer. Another simple test of renal excretion was afforded by the administration of a measured amount of water and the determination of the amount eliminated in a given length of time. If less than the normal amount was excreted, renal disease and diminished function were indicated. Two other simple tests might be used to reveal functional impairment occasioned by contracted kidneys. The first stage was shown by a loss of power to concentrate the urine. A healthy individual placed on a very dry diet for twenty-four hours would show a rise of urinary specific gravity to 1.030 or 1.040. In contracted kidney, a patient placed on a dry diet might excrete a urine having a specific gravity not exceeding 1.011 to 1.013. The second stage consisted of a loss of power to dilute the urine. Normally the ingestion of a large amount of water would result in a reduction in the specific gravity of the urine to 1.003 to 1.005. If this power to dilute the urine was lost, it consti-

tuted evidence of a more advanced stage of disease. Impairment of the kidney function was indicated by the following findings: Nocturnal polyuria (over 750 c.c.). A tendency to polyuria throughout the entire period, the volume of urine equaling or surpassing the amount of liquids ingested. Fixation of the specific gravity within narrow limits; in advanced stages the maximum variation might not exceed 1 or 2 degrees. Fixation in the two-hourly quantity of urine eliminated. Absence of the diuretic influence of food ingestion. If the night urine diminished to within normal amounts, it would show a low nitrogen content and low specific gravity. There might be a marked retention of both salt and nitrogen. The phenolsulphonphthalein test was one of the simplest and probably the best and withal the most reliable test for kidney excretion. It could be made by any practitioner. Convenient ampules containing slightly more than the required amount of the solution of 6 mg. of the dye to each 1 c.c. of fluid might be kept at hand. The bladder should be emptied, at least 500 c.c. of water taken, and exactly 1 c.c. of the solution administered hypodermatically. At the end of one hour and ten minutes and again at the end of two hours and ten minutes the urine was voided and separately saved. The amount of dye in each portion of urine was easily estimated by means of a colorimeter or by comparison with standard solutions of known strength.

Clinical Reports on Twenty-five Selected Cases of Renal Disorders Illustrating Various Functional Tests.—Dr. H. W. JONES presented a series of illustrative and typical cases of various forms of nephritis, grouped according to their prominent clinical features, in which careful studies of the blood chemistry, specific gravity fixation determination, urea test, and phenolsulphonphthalein tests had been made, with a view to determine their value, relative and absolute, and the correlation which they might show with clinical findings and ordinary urine examinations. An attempt was made to determine their relative value under different circumstances and to correlate them with the clinical findings. Certain conclusions were drawn in these and other similar cases and certain facts regarded as of practical importance bearing upon the etiology, diagnosis and future course of renal disease were indicated in the course of the case reports. The cases were presented in groups, according to the following plan of classification: Group I. Bichloride of mercury poisoning, with acute nephritis. Group II. Primary acute nephritis. Group III. Acute intercurrent nephritis, an important clinical group, many individual cases of which are often thought to be primary. Group IV. Chronic nephritis with cardiovascular disease, the largest and most important clinical group which we encounter in medical practice, showing many variations and combinations of different degrees and manifestations. Group V. Chronic nephritis with uremia, illustrating both the acute and chronic forms of the latter. The following conclusions were submitted: The ordinary examination of the urine does not give dependable evidence of renal disease. In many cases the urine examination yields almost negative results, in the presence of marked functional impairment. In other cases, the urinary findings indicate marked disease, which conclusion is not supported by functional tests. Renal lesion of a focal or patchy character, or an extraneous influence due to cardiac failure may be the explanation. A few cases were discharged much improved, both clinically and functionally, in whom there were marked and persistent urinary findings. The symptoms of renal disease, while of very definite diagnostic value, are not an absolute indication of the degree of functional impairment. This statement is especially applicable to the cases of moderate severity. Twenty-two of the cases were symptomatically much improved, while only eight were improved both functionally and symptomatically. The functional tests are a more exact means of estimating the prognosis than either the clinical symptoms, or the examination of the urine. The functional tests are the best guide as to the subsequent management of the case. The estimation of the blood nitrogen is of value only in cases of advanced nephritis. In all of the cases, except two, the blood nitrogen was increased only with a reduction of the phthalein output to 40 per cent or less. Some investi-

gations place the normal creatinine as high as 2.5 mg. per 100 cc. In the three fatal cases, only one gave a value above 2.5 mg. Several of the particularly severe cases showed creatinine at about 2 mg. and on discharge, the amount was unaltered, or even slightly increased, and this finding occurred in cases improved clinically, and in the presence of a reduction in the other nitrogen elements of the blood. Most of the cases had a creatinine content of 1 mg. to 1.2 mg. The amount present has some prognostic value. Those cases in which high values occur should receive a more guarded prognosis. Uremia, and uremic symptoms, are not dependent upon nitrogen retention. In a case of acute nephritis with severe uremic symptoms, the blood nitrogen elements were only slightly increased. In case 19, with well developed uremia, the blood nitrogen was normal. In two fatal cases of uremia, there was only a moderate increase in the blood nitrogen. In the fatal case of mercury poisoning, the blood nitrogen was greatly increased, but uremic symptoms were absent. Nocturnal polyuria was an important early symptom of nephritis. A disturbance of the normal ratio between the amounts of the night and day urine occurred relatively early; with improvement there was a tendency to resume the normal ratio. The urea concentration test was probably of value in hospital work, but the test was comparatively recent, and additional data must be accumulated before its general acceptance would be justified. It was evident from a study of the results of functional tests in various cases that in some instances they did not satisfactorily determine the renal status. Occasionally unmistakable clinical evidence was not in accord with the functional tests. On the other hand, the functional tests evidenced much greater impairment than was shown clinically. In many cases it was found that the different functional tests did not yield uniform indications of impairment, or that the results were disproportionate. It would appear, therefore, that the best results were to be accomplished by the use of more than one test instituted at various periods and the results of each considered in a final analysis. From the point of view of both availability and reliability the best test was the phenolsulphonophthalein. It had proved accurate and reliable; it was easily carried out in both hospital and private practice. The two-hour fixation test had seemed to him the test of second choice; in some cases, indeed, the first choice. It also had the merit of availability, as well as dependability. It was most useful in detecting chronic contracted kidney, the most frequent form of renal disease. In the ordinary examination of urine, slight findings with a low specific gravity were of more significance than more marked changes with a high specific gravity. Many cases of acute nephritis which were apparently primary were in fact intercurrent, the chronic disease being unsuspected, and resulting in lowered resistance and susceptibility to infection. The importance of a knowledge of these facts bore upon the future management. Cardiac failure or weakness developing in the presence of only moderately advanced renal disease might result in marked renal disturbance without obtrusive evidences of cardiac failure. Clinical observations would seem to indicate that blood pressure varied with the renal function, tending to rise with retention and fall with improvement, provided the cardiac factor remained constant.

DR. A. I. RUBENSTONE said that the essayists seemed to take the stand that the phenolsulphonophthalein test was nearly as good as an estimation of blood nitrogen with reference to kidney function. As a matter of fact his own experience had proved that this was not so. He felt that protein estimation was far more important so far as kidney function was concerned than the phthalein. Phthalein gave an estimation of kidney function for the time being and did not tell what was retained in the blood. Furthermore, it was a foreign substance which the kidney was not used to excreting. He believed that before surgical operations were performed the estimation of nitrogen was a very important factor.

DR. A. E. ROUSSEL said that the diagnosis of kidney lesions in many instances could not be made by urinary examinations alone. Not only the function tests were of importance, but the blood chemistry was of great importance as regarded both diagnosis and prognosis. Indeed one could well understand that even cases of high blood pressure might be essential hypertonia not

associated with sclerotic kidney. The condition could only be told by blood chemistry and ophthalmological examination. Dr. Roussel said that he disagreed decidedly with the reader of the second paper. He expressed his astonishment that he had found relatively low counts in his creatinine counts, especially in the fatal cases. The urine might be markedly improved in the percentage of albumin and diminution of casts and yet 2 to 4 mg. of creatinine still remained persistently present and it was a fact that in a fairly large number of cases he had never known a patient to live more than one year after continued presence of 4 mg. of creatinine. Both the phthalein and the fixation test were of use. The fixation test with the total quantity of night and day urine was more useful than the phthalein, which was more influenced by extraneous circumstances. Nobody had a right to diagnose a case of kidney disease without blood chemistry and functional tests and in some instances with the assistance of an oculist. He considered the creatinine test of greater prognostic value than any of the others yet mentioned.

DR. LEON HERMAN said that he regretted that neither of the readers of papers went into the subject of kidney functional test from the surgical point of view. The urologists and surgeons had contributed considerably from the standpoint of clinical observation of the behavior of kidneys when traumatized by anesthesia and operations on the urinary tract. There was a great deal to be learned about kidney function from the surgical standpoint. We did not know much about the inherent capacity of the kidney to withstand trauma. From the surgical standpoint, while all of these tests were of value, he agreed with Dr. Roussel that the tests of excretion are of less importance than the tests of retention.

Stated Meeting, Held April 13, 1921.

THE PRESIDENT, DR. GEORGE MORRIS PIERSON, IN THE CHAIR.

Studies Concerning the Influence of Arsenical Applications upon Cutaneous Tests.—DR. ALBERT STRICKLER read this paper, in which he said that for a long time the medical profession had felt the urgent need of a simple and certain diagnostic test for syphilis. The wide distribution of lues, the fact that syphilis could and did simulate many other diseases, and the fact that even the expert was at times baffled in the diagnosis had emphasized the necessity for a simple and certain diagnostic test for lues. For the study of this problem the author had selected fourteen patients from the Skin Dispensary of the Jefferson Hospital. At least two Wassermann tests were made upon each patient, both of which had to be negative before they were selected for the experiment. The study warranted his statement that arsenic probably induced susceptibility of the skin in nonsyphilitic individuals so that the administration of arsphenamine might cause the production of a positive luetin test in nonsyphilitics. The repetition of the luetin test in nonsyphilitic patients was capable of producing positive luetin reactions in about 21 per cent. of the subjects. The intravenous administration of arsphenamine seemed to stimulate the production of a luetin reaction in nonsyphilitic patients, this occurring in 52 per cent. of cases. The intravenous administration of sodium cacodylate acted in the same fashion but more feebly.

DR. THOMAS MCCRAE of Philadelphia said that this work made it necessary that we should revise a great many of our ideas regarding specific reactions. The positive Wassermann reaction following arsphenamine injections as noted by Dr. Strickler were rather disturbing. It was thought that some reactions had been fairly definitely established. He had seen the vast majority of these cases and there could be no question but that there was a marked reaction. These cases had come to the Dermatological Clinic and had a skin condition to begin with. Did that render them more likely to react to arsphenamine? That could not be answered until similar conditions were considered in individuals without any skin disease whatever. The bearing of this with reference to the treatment by arsphenamine was very evident. We have controlled our treatment of syphilis largely by Wassermann re-

actions, but that had evidently gone by the board because patients to whom arsphenamine had been administered were apt to give positive Wassermann and positive luetin reactions whether they had syphilis or not. This he hoped would stimulate a great many men in different parts of the country to take up similar work because it was only when we had a large body of statistics, such as no one man could produce, that we might perhaps get a little light on the subject.

Dr. RANDLE C. ROSENBERGER of Philadelphia said that he had been privileged to see most of these reactions with Dr. Strickler. It was very hard to explain the positive reaction in these cases. He would not attempt to explain it. A great deal more work was required on this problem of the specificity of the treatment by arsphenamine.

Influenza and Epilepsy—Their Reciprocal Influence.—Dr. ALFRED GORDON read this paper, in which he said that in studying epilepsy in all its phases for a number of years one was struck by the fact that an infectious process occurring in an epileptic had a decidedly favorable influence upon the frequency and severity of epileptic seizures which were sometimes totally suppressed during the febrile period of the infectious disease. It seemed that the reactions of defence against toxins which had an elective action upon the nervous system exerted a favorable influence upon epilepsy. The relation of infectious processes to the course of epilepsy had been studied by the writer in a series of twenty-five cases of influenza. A complete suppression of convulsive attacks was observed in each case. As soon as the febrile state began to subside there was a tendency to a return of the convulsions. For some time after the temperature became normal the attacks were lessened in severity. These observations indicated that a toxic principle elaborated during an infectious state was capable of neutralizing the toxic principles existing in the humors of epileptic individuals. Sero-therapy was therefore indicated and the problem was to produce such a neutralizing biological product.

Dr. JOSEPH SAILER said that we had all observed the effect of emotional shocks of various kinds and operative procedures in stopping epileptic attacks. At the time he had been a resident at the Philadelphia Hospital there was great enthusiasm about the cure of epilepsy by removal of part of the cerebral cortex. One of his fellow-residents conceived the ingenious idea that other measures would be as successful as trephining the skull and he bled some of the epileptics who had not been operated on and some who had had an operation, and the result was that after venesection, which had never been considered seriously, most of these patients recovered for a time from their epileptic attacks, but shortly thereafter they all recurred in the usual manner. It occurred to him that possibly a severe infection might have the same mental effect upon epileptics and therefore it would perhaps be wise to look into the subject a little more thoroughly from this point of view before we indulged too liberally in the various forms of serotherapy for the purpose of arresting temporarily the attacks of epilepsy. It was a very interesting observation that severe infections with high temperature might have this inhibitory effect.

Dr. THEODORE H. WEISENBURG said that while he disliked very much to question Dr. Gordon's work he thought his conclusions were far-fetched. He took for granted that the patients would have had fits if they had not had fever. How could one say that that was an indication for any particular form of therapeutics? That was vicious propaganda. Fits might come on or might be absent for some time. He had never been more impressed with that than at the Elwyn Colony for Epileptics, where thirty patients had been selected for taking moving pictures. Those having fits daily or even two or three times a day had been selected. He went out with the moving picture apparatus, and it was taken for granted that they would have fits, and not a single patient had a fit that day. He went back the next day, when the patients had become accustomed to the camera, and they had the usual number of fits.

Neurological Symptoms Occurring in Pernicious Anemia Especially Antedating the Appearance of the Blood Picture.—Dr. THEODORE H. WEISENBURG read this paper, in which he said that during the past two

years he had seen in con- ten patients, in most of whom the dia- had been supposedly either tabes or some other spinal cord disease, and in whom he had made the diagnosis of a postero-lateral sclerosis occurring with pernicious anemia before the blood changes had made their appearance. He had the impression that the medical profession at large was not familiar with the fact that in pernicious anemia nervous symptoms might appear first, although in the majority of cases the nervous symptoms came on either at the same time or following the blood change. It was probable that the nervous system was attacked in two ways, either directly by the toxins or by metabolic changes produced by the anemia itself. Practically without exception the patients complained of sensory phenomena, such as numbness, coldness, or burning sensation, which first occurred in the feet and gradually extended upward to the thighs and abdomen and the upper limbs. These symptoms should at once arouse the suspicion of the presence of pernicious anemia. Later the patients complained of weakness in the legs, cramps in the calves, disturbance of the sense of smell, taste, and hearing, with the presence of dizziness and roaring in the ears. One patient objected very much to the smell of newspapers and dogs. At this stage there was nearly always a spastic or ataxic gait, diminished reflexes, and at times the Babinski sign. Mental symptoms were present in about 40 per cent. of the cases, ranging from mild depression to violent maniacal outbursts, irritability, delusions, hallucinations, apathy, and severe melancholia. Recent examinations showed disease to be present in the brain, spinal cord, and other parts of the nervous system. These changes were not specific and were similar to those found in chronic intoxications. The blood vessels showed swelling of the intima and some proliferative changes. The brain, as well as the posterior and lateral columns of the cord, showed areas of degeneration. Prognosis was very poor. In one case the disease ran a course of three years, but in all others the patients died within one and a half years after the onset of the symptoms.

Dr. JOSEPH SAILER said that pernicious anemia was a mysterious disease; it was just as mysterious at the present day as it was at the time of Addison's discovery. Inasmuch as closely related forms of anemia were due to intestinal parasites it caused one to question whether there might not be undiscovered parasites operating as the cause of the idiopathic forms of pernicious anemia. The interesting thing about pernicious anemia which we were gradually learning was that the blood picture was not by any means the sole feature of the disease. There were both mental and nervous symptoms, due practically to the same cause, that was, unexplained degenerative lesions in the central nervous system, which had the pathology of a chronic sclerosis of the central nervous system.

Wet Grinding a Dangerous Occupation.—That grinding and polishing by the wet process, instead of being, as has been generally supposed, a dustless and innocuous process, is, under certain conditions, a dusty and exceedingly dangerous employment, seems to be demonstrated by a report prepared by Dr. W. Herbert Drury of the U. S. Public Health Service, after an exhaustive investigation conducted in a large axe factory in a Connecticut town. Dr. Drury shows that the death rate (1900—1920) from tuberculosis among the workers in the grinding and polishing shops, who for six hours a day breathe an atmosphere of relatively high humidity heavily laden with acutely angular hard siliceous dust, is 19 per thousand, and that of other workers in the same mills (but not in the grinding or polishing shops) is only 1.6. Furthermore, the rate in the general population (not including the mill workers) in the three villages from which the workers are drawn is 1.2 and in the whole State of Connecticut is 1.5 per thousand. Grinding has long been recognized as gravely hazardous both in Europe and in the United States. Counts show that there are an average of ten times as many dust particles in wet as in dry grinding shops; and the report recommends the substitution of a dry grinding process, properly protected by the installation of exhausts, for the present wet process.

Miscellany.

AN APPRECIATIVE OUTLINE OF MEDICAL PROGRESS.

BY JOHN COGHLAN, M.D.,

NEW YORK.

IN considering the humanitarian aspect of our civilization, which is so commonly characterized as negative rather than positive from the angle of enlightened progression and which avowedly leaves much still to be desired from a general standpoint, it is perhaps in order to point out that the ordinary practice in the formation of a judgment on this score is either to ignore entirely or to accord scant credit to the solid advances which have been made in the field of medicine and surgery. It must be conceded by any one who has accorded the matter a fair hearing that these achievements of themselves eloquently testify to the vast amount of arduous labor and intelligent research that have been expended throughout the centuries by the medical profession on behalf of the conservation of life, and at the same time undoubtedly furnish a contrast with other phases of our common life, which tend toward the destructive rather than the constructive side of humanitarian endeavor, that is not only striking but highly commendable to the ethical impulses and standards of the medical profession.

The situation in this respect is more clearly defined perhaps when, by way of illustration, we reflect that in all the ages which have passed since Socrates was required to drink the hemlock, it is extremely doubtful if a more humane method of executing the death penalty prescribed by the law has ever been devised or practised, with the possible exception of lethal gas as just recently proposed in Nevada; and then when one considers even casually what is involved from the humane standpoint in such methods as the guillotine, hanging, shooting, electrocution, etc., it is unquestionably difficult to discern the existence of any grounds upon which to base a claim of progress in this direction, to say the least. Then, again, when we turn our attention to the institution of war, which, prior to the summer of 1914 was supposed to be on the wane, and it was even claimed by many eminent authorities that it was impossible of recurrence on any extensive scale; nevertheless it has again prostrated the world after a five-year period of destruction and desolation such as was never before enacted in the history of mankind, and it indeed offers indisputable ground for the common plaint that our civilization is deteriorating instead of advancing. But, while the conditions cited must be patent to every careful observer and are accordingly deplorable, from the viewpoint of what may be termed the orderly course of human evolution, it is nevertheless true that a larger and more matured vision inevitably enforces a recognition of the fact the the world, as a whole, has been and is steadily though slowly advancing, more prominently perhaps in some given department at the moment than in others, and therefore it is quite essential to the formulation of any proper judgment that due notice be taken of all factors and particularly those that have notably contrib-

uted to the accomplishment of real human progress.

The chief purpose of this article is to point out briefly a few of the more noteworthy advances which have been made in medicine and surgery, and which alone conclusively dispose of the charge so frequently and lightly made that the trend of our civilization is retrogressive rather than progressive in its character and results. For the statement of our case, and without harking back to the more ancient days of Esculapius and Hippocrates, it will suffice to begin with the comparatively modern period when William Harvey discovered the circulation of the blood, in the seventeenth century. We are aware that prior to this event it was the accepted belief that the blood vessels contained air, and the records of Harvey's labors inform us of how he, at the expense of much privation and sacrifice, journeyed into South Africa and dissected corpses hanging from the trees in his quest for the knowledge which came to the medical profession as well as to the world at large through his great discovery. Then, a couple of centuries later, came another epoch-making discovery in the form of anesthesia, the significance and benefits of which from the viewpoint of conserving human life and suffering are truly inestimable, to say nothing of the invaluable research work which its use has made possible and the achievements of which have contributed so solidly to medical and surgical practice and advancement. Just picture for a moment the old-time surgeon doing an operation for stone in the bladder, with the powerful six-foot nurse sitting in a big armchair, taking the patient in his lap and holding him by the thighs, while another nurse held his hands from behind over the back of the chair, as the surgeon meanwhile cut directly into the bladder, and it is not difficult to imagine the suffering as well as the high mortality that must have accompanied this and other forms of surgery practised in earlier times, which the use of a few drops of ether or chloroform would not only have greatly alleviated but obviated entirely for the most part.

Again, consider the great and permanent benefits that have resulted from the practice of vaccination, what antitoxin has been the means of accomplishing in the way of saving the lives of children and adults as well, and also the beneficent results that have been attained in the treatment of syphilis by and through the intravenous injections of salvarsan. And last, but by no means least, think of the great boon to both the pregnant mother and the attending physician that has come as the result of patient research into the nature and function of the pituitary gland. Let us imagine, if we can, what must have been the sensations of the expectant mother in delayed labor in former times, confronted by the general practitioner, who, with the conventional bald head and shaggy beard, was generally more expressive than elegant, and, to make the occasion more impressive as well as formidable, armed with a pair of axis traction forceps nearly as long as the patient herself. To-day a hypodermic syringe with a few drops of a solution of pituitary extract achieves the desired result in at least 90 per cent. of the cases which

are not characterized by extreme dystocia, and entirely free from the adverse conditions of shock and agony formerly engendered. These are but a few of what may be called the high lights along the pathway of achievement in the realm of medicine and surgery, and yet in the face of such a brilliant record the assertion is still current that there has been no real advancement from the viewpoint of human welfare!

It would be hardly fitting, to say the least, to conclude an article of this character without making respectful and grateful mention of the medical conferences that are held from time to time, where members of the profession give freely of their knowledge and experience, covering both general and special research work, involving the labors of years, and where all members are welcome and privileged not only to listen but to take part in the discussions, as well as in the freer social intercourse which the collations usually served after the meetings always provide. The educational value of these conferences is indeed incalculable, and the greater vogue and scope of these gatherings alone mark a very distinct stage of progress in the medical field. It may also be permissible to point with pride to the high place in the life and esteem of the community that is enjoyed by the medical fraternity, both by virtue of the humanitarian character of the profession and also as a deserved recognition of its valued service to the cause of human progress. There is hardly a day that passes in which some tribute is not paid to the memory of some member of the profession who has passed away, for all good deeds do live and find nourishment in the hearts of those who have been blessed by them, and what to the writer is true of such illustrious members as the late Professor Joseph H. Raymond, as well as his able associates, McCorkle and Jewett, is likewise applicable to the individual experience of the profession at large, for even time that wipes away grief and pain does not so readily efface from the memory the kindly and helpful deeds of the humblest physician.

137 EAST FIFTY-SECOND STREET.

Surgical Corporations in Old France.—Raffray has been contributing a serial article on the history of medicine in Northern France and in the concluding number of the *Gazette des Praticiens* for April 1, 1921, xxviii., 507, he writes of the ancient guild of surgeons. The latter were simply artisans like other mechanics, and in each city they were grouped into these corporations, the patron saints being Cosmas and Damian. There were collected into one single body the master surgeons, surgeons, and midwives, and apparently those who dwelt in the smaller towns and villages, chiefly midwives, affiliated with the surgeons of the nearest large town. The oldest corporation of which there is any record in Northern France was at Cambrai in 1366, but this does not mean that there were not others contemporary, nor older ones, for the guilds in question were known to have been completely organized by the middle of the fourteenth century. Of statutes dealing with these guilds none is known before 1632, and the early ones after that date had to do only with feasts of the patron saints. Every year,

on Sept. 27, the feast day of SS. Cosmas and Damian, all of the members of the surgeons' guild dressed in their best and assisted at a solemn high mass, vespers, and, on the following day, a requiem mass for dead members. The offices of the surgeons remained closed and only the most urgent calls were heeded. These guilds lasted the duration of the old regime, and as late as 1770 there are documents on guild administration. The Dean was president of the guild and also termed surgeon-in-chief. His was the right to convoke assemblies and he was responsible for keeping the minutes of the transactions. Under him was a surgeon who was known as the provost, charged with policing the corporation, and a recorder, who acted as secretary. The Dean headed the Board of Examiners and inducted the newly elected members into the guild. The "surgeon," as distinguished from the "master surgeon," and the "midwife" had no votes. All members had to discharge scrupulously their religious duties on Sundays and holy days. Ethics were recognized and a member could not take over a patient from a fellow member unless authorized by the latter, or in his presence, this last amounting to a consultation.

Pozzi's Family and Early Life.—From an eulogy by Faure on his colleague Pozzi, which appears in *La Presse Médicale* for March 9, 1921, xxix, 20, we learn that the father of the subject, a Protestant clergyman, spelled the name Pozzy. The family was originally Italian-Swiss, and its home-
stead was in the Valteline valley in Italy. Religious persecution drove the Pozzis from Italy to Switzerland where Protestants then took refuge. They reached France before the Revolution and two brothers took part in the latter. The younger, Dominique, was the surgeon's grandfather. A pastry cook after the war he became the father of the minister, Benjamin, one of a dozen children. The latter married a woman of means and had five children, of whom the future surgeon was one. The comparatively early death of the mother caused Samuel to be brought up by the maternal grandmother, who lived to the age of 93. Pastor Pozzy remarried and one of the children by this second marriage was the physician, Adrien Pozzi. In 1853 the pastor had a call to Pau, and leaving his old charge at Bergerac took his son Samuel with him to place him in the local lyceum, he being then 12 years old. He finished his general education at Bordeaux, after his father had been called there. A Mr. Laboulbène having married a sister of the pastor, the son, afterward the well known physician of the name, was instrumental in forming the choice of career of medicine by his cousin Pozzi. Laboulbène's career in Paris as student and interne had been so brilliant that it was decided Pozzi should emulate him. In November, 1864, he joined his cousin in Paris and began his studies, but becoming involved in some trouble about the anatomical course he was disciplined by the Faculty. We hear nothing further until 1868, when he began his internate under Laboulbène. Not long afterward the German war broke out and his studies were interrupted until 1871, when at the age of 25 he began his career in earnest.

THE TEETH AND SYSTEMIC DISEASE.*

By W. GILMAN THOMPSON, M.D.,

NEW YORK.

CONSULTING PHYSICIAN TO BELLEVUE, THE WOMAN'S AND ST. BARTHOLOMEW'S HOSPITALS.

IN 1875 John W. Riggs advanced the theory that the disease which commonly bears his name, "pyorrhea alveolaris," was of local origin, due mainly to calcific deposits around the teeth. This directly controverted the earlier view upheld by E. Magitot and others that it is due to "systemic factors" owing to its frequent appearance in gouty and rheumatic subjects. For many years controversy over these opposing theories continued, and notwithstanding the description given by Wm. Hunter in 1900 of what he termed "oral sepsis," in causative relation to lumbago and other ailments, important works upon dentistry have appeared up to quite recent date in which no mention is made of systemic diseases as originating in bacterial infections derived from the mouth. Finally, the anomalous situation is observed to-day of lack of cooperation in many instances between dentist and physician, while, on the other hand, there is a group of extremists who advocate wholesale extermination of suspected teeth as a cureall for a great variety of constitutional maladies. Any observations, therefore, which tend to emphasize the importance of a subject, so often overlooked, should be of interest.

One difficulty in dealing with the problem is the undoubted fact that very bad infection in and around the teeth often may exist for years as a purely local condition. In Bellevue Hospital, for instance, where are treated so many poor and ignorant persons who are as careless of their mouths as of everything else, I often have been impressed by the number of patients met with who present no evidence of having had symptoms at any time which might be ascribed, even remotely, to diseased teeth and gums although the teeth were in very bad state. In contradistinction are the cases one encounters where a single chronic alveolar abscess found among otherwise normal teeth (at least in so far as root disease is concerned), forms the explanation of serious ill health. For example, a young man came to me early last winter who was studying in a business college. For several months he had felt continuously tired out with vague muscular pains and frequent severe headache for which his habits of life and general physical examination suggested no explanation. Being suspicious of the

mouth from which he already had lost several teeth, I referred him to Dr. Irvin H. Beach for radiography, who reported as follows: "It is interesting to note that when looking over this patient's teeth it did not look as if there was anything out of the ordinary, but the radiograph shows a piece of a root left in a place that appears perfectly healthy from a visual inspection." Upon removal, however, this root fragment proved to be a focus of chronic infection, and without any other treatment within a very short time he became entirely well and has so remained for several months. This is merely a type of what one often sees where similar nonextensive conditions are present, and illustrates the fact that the quantity of pus formed is not definitely related to the seriousness of systemic symptoms. Hence the patient does not seek the dentist, or if he does go to him, he says nothing of his general health, and if he consults his physician he says nothing of his teeth, having no conception of any possible malign relationship.

That a very bad condition of the oral cavity long may exist without giving rise to any systemic symptoms is explainable through one or the other of two hypotheses. First, the patient may originally possess or may have acquired a complete immunity against systemic infection. Secondly, there is known to be great variation in the virulence of different strains of the pyogenic germs involved.

It also may happen where a seriously diseased condition of the teeth may have existed for years without inducing systemic infection, that some intercurrent disease, of wholly different origin, so lowers the patient's resistance as to give the mouth germs opportunity, flourishing in the vascular gum tissue, to overcome the victim's previously acquired resistance. The great importance of this fact is too often ignored where serious operations are to be performed, whereas whenever time permits the infected mouth should first be put in order. At the Mayo Clinic it is customary in all such cases to first make the mouth aseptic, and the need of this is emphasized through the fact that the enfeebled patient, during a prolonged convalescence, necessarily neglects the care of the mouth, so that even a slight degree of local infection may rapidly extend and become generalized. As Dr. Beach has well said: "In cases where the bacteria in the oral cavity have absolutely no relation to the diseased area to be surgically removed, even then primary dental treatment is an essential procedure, for very often all that is necessary for the septic bacteria to become disastrously active is to have the natural resistance to the inroads of these virulent germs lowered and resultant complications arise."

*A paper read before the Practitioners' Society, May 5, 1921.

Much light may be thrown upon the matter by a brief reference to the pathology of pyorrhea and chronic alveolar or periapical abscess. The commonest varieties of germs found in these disease are the streptococci, pyogenes and viridans, and the staphylococci, pyogenes albus, aureus, and citreus, with staphylococcus epidermidus albus. Of these the streptococci, particularly the viridans, are present in the chronic alveolar abscesses, as compared with pyorrhea, in about the proportion of four to one, although in acute abscesses staphylococci are the common germs, according to Hartzell and Henrici, who also reported the viridans as present in 250 cases of chronic abscess.

The staphylococci associated with pyorrhea are often either very slightly virulent or may be completely avirulent. There are, however, many exceptions to this statement and a nearly fatal case of pyorrhea and abscess combined, presently to be reported, was due to a staphylococcus aureus.

Pyorrhea simplex begins as a gingivitis excited by continued irritation from calcareous deposits, a broken or uneven tooth surface, malocclusion, or an ill-fitting plate or similar source of injury to the gingival border, and the inflammatory process extends along the pericemental membrane to the alveolar sockets. The highly vascular gum bleeds readily and the periodic swelling of the gum due to pus accumulation causes curiously little pain, even when pus may be squeezed out in considerable quantity. Pyorrhea, therefore, having surface drainage as compared with the much less obvious root abscess may exist in extreme degree without occasioning systemic symptoms, other, perhaps, than digestive disturbances. As stated by H. B. Anderson "the condition is more readily recognized, and since the pus does not accumulate under pressure, efficient drainage, especially in the upper jaw, is more readily obtained." In the pyorrhea "complex" (so designated by Brophy), the highly vascular gum tissue is weakened by systemic disease, and the process is accelerated.

Wholly different are the lesions which lead to chronic root abscess. In a typical case, this is what transpires: the lactic acid-forming bacilli of the mouth produce the acid which gradually dissolves first the enamel and then the softer structures of the teeth. The exposed pulp then readily becomes infected by streptococci and the process extends through the foramen at the apex of the root canal to give rise to caries or even necrosis of the bone forming the root socket. Thus a chronic abscess develops, the contents of which is more or less completely closed off by a fibrous sac and is under pressure. A. D. Black has calculated that the teeth are subjected daily to a pressure which may amount to 1700 lbs. and Hartzell describes the sort of piston action produced in mastication by driving the tooth in or out upon the abscess, which tends to force the pus into the surrounding blood and lymph channels. A chronic abscess, if well walled off, may remain latent for a considerable time without causing systemic infection, when either repeated blows or a thinning of its wall may convert a localized process into a more or less serious general infection. Such infection, furthermore, is sometimes originated through the injury done in attempting to extract an intractable root. The elaborate gold caps

which formerly so often were placed to camouflage the remains of badly decayed root stumps are particularly vicious through masking trouble, and I have seen a number of patients recently who said that they had just been passed by the dentist as having everything in good order. From the outside there was only evidence of successful mechanical work. The dental instrument, tapping over the capped surface, revealed no pain or any evidence of continuing decay which all the time was slowly advancing. On being told to go back to the dentist and insist upon complete radiography, extensive bone involvement was evident, and the explanation of a variety of constitutional symptoms was revealed, which completely subsided after removing the cap and cleaning out the diseased area.

In illustration of how high to death it is possible to come through carelessness regarding the teeth, the following case record presents several unusual features.

The patient, a man of fifty-odd years, was in ordinary health until August, 1920, when he had a molar drawn which troubled him. He was told by the dentist that the cavity was in bad condition, but being relieved of the tooth, completely neglected further treatment. Shortly, thereafter, he began to fail in general health, but without showing definite symptoms until November, when his physician found he was having a septic run of temperature of low grade. He developed pain and vasomotor disturbances in the left leg, with several areas of anesthesia. When I saw him in consultation early in December, he was desperately ill, presenting a typical picture of advanced sepsis. The irregular temperature rose at times to 104° F. the erythrocytes had fallen to 3,200,000 and the hemoglobin to 70 per cent. but there was no leucocytosis. A dozen more or less painful large subcutaneous nodules were present upon the left leg. The teeth, which had just been radiographed, exhibited extensive infection around half a dozen roots, which in several instances had involved the bone. He was so ill that there was some hesitation in removing any of the teeth for fear that the infection might be made worse through trauma, or that he might not withstand the shock. But believing it to offer his only chance of recovery, I advised that the two worst teeth be drawn. His dentist was called in and this was done. Temporary abatement in the fever followed, but in a few days the temperature rose again to 104° F. and further nodules appeared upon both arms. The temperature elevation continued with daily fluctuations of from two to four degrees, sometimes being subnormal. The metastatic nodules in the right arm suppurated and although they were incised, an extensive slough followed which involved the subcutaneous fat, and reached from immediately below the axilla nearly to the elbow and about half way around the circumference of the arm, necessitating subsequent skin grafting. By degrees the remaining infected teeth were extracted and the cavities disinfected by daily treatments. After ten weeks the temperature gradually subsided, but it was more than three months before it remained entirely normal. *Staphylococcus aureus* was obtained from the infected jaw, from which I advised making an autochthonous vaccine of which ten doses were given, ranging from fifty to two hundred millions. The patient has now recovered after six months with the exception of some weakness in the left leg, stiffness of the right arm and a small area still requiring skin grafting.

This staphylococcus case is of interest through the absence of localized joint lesions of the type so common in the *Streptococcus viridans* infections.

Lately I have met with a quite similar case although it was less nearly fatal. The septic temperature lasted six weeks and there was an erythema nodosum upon the legs, but without suppuration. After withdrawing six infected teeth the

man recovered completely. Previous to the onset of fever he had endured a long period of increasing malaise.

It is perhaps debatable how far the vaccine aided in saving the first patient's life. I can only say that he was failing very fast when he first received it, and promptly began to improve thereafter. I am inclined to believe that it benefited him. Howland and Hoobler have reported three cases of general septicemia cured by use of vaccine made from this same organism, the *Staphylococcus aureus*. In these cases, however, the infection originated not from the teeth but the tonsils. It is well known that vaccine treatment often is successful in the chronic arthritis cases of viridans origin. A patient of this latter type I observed for several years. She had, when first seen, a generalized crippling arthritis of the major joints which finally, after three years, had made her almost completely bedridden. The case was complicated by the fact that the viridans was obtainable not alone from badly infected teeth, but from the secretions of the nose and nasopharynx. Extensive pyorrhea was present in addition to pericemental apical abscesses involving half a dozen teeth. On two occasions the viridans was obtained from cultures of the stools, the germs having been swallowed. I referred the patient to Dr. John H. Richards for vaccine treatment. After extracting the offending teeth two vaccine series were administered, one of 40 injections, the other of 20. The patient is now able to walk and is markedly improved in every way. This is cited as the type of case which a few years ago would have been treated by salicylates or iodides or similar medicines and by local applications of all sorts, such as baking, and the use of blisters, fomentations, and liniments. It is my belief that as time goes on we shall see no more of the typical cases of advanced deforming polyarthritis of this kind, which formerly were so prevalent in our hospital services and which proved so rebellious to treatment.

It is by no means claimed that all these cases arise from alveolar infection, for in some instances, like that cited above, the viridans or similar germs may be found in the nasal sinuses or tonsils, and just now there is an interesting wave of tonsillectomy, but in any given case of the type of polyarthritis referred to, thorough radiography of the teeth usually will demonstrate one or more pericemental abscesses. How often it happens in the aged that the progress of this disease is arrested spontaneously when they lose their teeth and it is rarely, if ever, observed in the very aged who for many years have worn plates.

Recently a man came to me, as he said, "merely to show how well he was." Six months before he had come with a pain in the right hip joint and which extended down the sciatic nerve. It had lasted for several weeks and while not incapacitating him, was very distressing. Finding no other plausible explanation of the pain I looked in his mouth where I found four gold capped molar and pre-molar stumps. I told him that although it was not absolutely certain, I suspected his teeth were the source of trouble and showed him some typical radiographs of root abscesses beneath crowned teeth which I keep in my desk to illustrate to pa-

tients what may go on beneath a surface which appears, as in the patient referred to Dr. Beach, free from probable infection. He, however, frankly said he did not believe me and went to an orthopedist who treated him for several weeks with external applications and medicines, under which régime he grew steadily worse. He finally took my advice and the x-ray showed the suspected pericemental abscesses. The teeth were extracted, in a few days the pain wholly disappeared and he came in to give me the satisfaction of an "I told you so!"

I have not met with many cases of septic endocarditis which could be referred unquestionably to dental infection, but I might cite a number of cases, particularly in the aged, of marked cardiac weakness and irregularity which completely disappeared under proper dental treatment. One such example must suffice. This patient was a woman of 82 years whose heart action appeared to indicate a typical myocarditis. Like many aged persons she had seriously neglected the care of the body and particularly of the teeth, until she acquired a most foul pyorrhea. As all ordinary remedies failed to improve either her disordered digestion or arrhythmic heart action, I arranged to have a dentist visit her daily and treat the pyorrhea. This he did so successfully for several weeks that all symptoms disappeared and she was restored to a fair measure of health with normal digestion and heart action. It is my impression that such cases of disturbance of digestive and cardiac functions are more often due to pyorrhea than root abscess, although these conditions of course often coexist. On the contrary, it is the root abscess which is more often responsible for disease or functional disturbances involving the joints, muscles, and peripheral nerves.

Another typical cardiac case, not to be classed as "aged," for the patient is not above sixty, is that of a woman who, for several years had suffered from attacks of tachycardia and arrhythmia with slightly increased blood pressure, dyspnea on exertion, and great lassitude. These attacks became so frequent and alarming to her, being brought on by the slightest muscular effort, that she was constrained to abandon most of her activities and spend much of her time lying down. I found her teeth suggested the possibility of root abscess, several molars having been extensively filled, and despite her statement that her dentist had told her there was "no trouble", I insisted upon having the teeth radiographed. Two large chronic root abscesses were revealed, the teeth were extracted, and the patient is now entirely well, having remained for several months free from attacks which formerly were of more than weekly occurrence.

I would not be misunderstood as advocating promiscuous extraction of teeth for the cure of all manner of systemic diseases, but in cases of chronic arthritis or polyarthritis, neuralgic pains, lumbago, persistent extreme muscular fatigue, and similar conditions in which no obvious cause is demonstrable, it is well to insist upon radiography of the teeth, despite the fact that no pain in the mouth exists and that there is not necessarily any visible active trouble above the gingival border. This insistence applies also to certain types of cardiac irregularity and undue frequency not referable to organic disease, and to much gastrointestinal func-

tional disorder. Sins of omission in regard to root extraction are likely in the main to be worse than those of commission, and the periapical abscess, particularly if it has begun to cause caries or even necrosis is not likely to cure itself. Although the local lesion may remain inert for a considerable period, as regards exciting systemic symptoms it is nevertheless a perpetual menace, and may at any time give rise to most serious, if not actually fatal consequences.

I am well aware that there is nothing new in this presentation of the subject, but the many deplorable consequences of neglect of the matter which I am constantly seeing, justify the need of emphasizing closer cooperative work between the physician and dentist. To this end occasional joint meetings between medical and dental societies are desirable, and physicians should furnish dentists with abstracts of the histories of cases referred for dental treatment in order to stimulate greater thoroughness in examinations and better mutual understanding. Patients also should be instructed as to the possible causative relationship between the types of systemic disease above referred to and dental infection and be made to insist upon radiography of their teeth in connection with all extensive dental treatment which may be indicated. By this simple precaution much serious illness may be averted.

142 EAST SIXTY SECOND STREET.

SERUM TREATMENT AND MANAGEMENT OF LOBAR PNEUMONIA.*

By W. W. HERRICK, M.D.,

NEW YORK.

I RECALL, several years ago, observing the late Dr. Edward Janeway in consultation in a case of lobar pneumonia. The patient in question was being given food at two-hour intervals, water at one-half-hour intervals, and medicine every hour. There were sponges and poultices, frequent examinations by physicians, and unremitting ministrations of solicitous family and friends.

This harassed patient gazed up at Dr. Janeway and said, "Well, what are you going to do for me?" Dr. Janeway replied, "We are not going to do anything but let you rest for four solid hours." "Doctor," said the patient, with a sigh of relief, "you are a wonder. That is what I need, rest." Those who remember Dr. Janeway's habit of summing up a situation in one brief phrase will appreciate his remark in this instance: "They try to do too much."

In the treatment of pneumonia, I believe we try to do too much. Meddlesome interference robs the patient of the rest of which he stands in need. Stimulants often irritate and banish sleep. Ill-judged and ill-timed examinations are an undue burden upon cardiovascular and respiratory systems staggering to the point of collapse. We must remember that nothing we can do to combat the infection compares with what the patient can do for himself. A few particles of the patient's own antibody are worth all the drugs in the world.

*Read before the Medical Society of the County of New York, March 28, 1921. (See page 982.)

I believe the correct attitude to take in considering the management of an acute infection is this. Of those ill a certain number will get well no matter what we do, another number will die no matter what we do, but intermediate between these two classes is a class—perhaps a large class—in which the scale is delicately balanced, inclining now toward recovery, again toward a fatal issue. In this class every wise effort is worth while, and the feebleness of our attempts may turn the scale in the desired direction.

The patient is running a race in which much is demanded of heart, respiratory system, and of the internal or cellular respiration, and in which these vital factors are severely handicapped. Our first object is to place upon these mechanisms no needless burden and to provide against every purposeless expenditure of energy. Two attendants should be at hand to spare the patient all effort in the care of necessary functions. Examinations should be made quickly, not too frequently, and without needless disturbance or effort on the part of the patient. Visitors should be excluded and long periods of rest and quiet secured. Apprehension and wakefulness are well combated by generous doses of chloral hydrate and the bromides given by rectum. Opiates, I choose to avoid because of their certain effect in retarding peristalsis, and their tendency to increase distention. However, if other sedatives, and local applications of heat or cold, poultices, plasters, and the like, do not relieve the pain of pleurisy, a single hypodermic of codeine or of morphine may be used to break up the pain and apprehension of the early stages. Plethoric, full-blooded individuals with labored breathing and distended veins may profitably be deprived of twelve to twenty ounces of blood.

There is no satisfactory evidence that any of the oft-exploited routine medicines, such as camphor, quinine, or creosote derivatives, are of use. At present digitalis is in high favor. Its use has the weight of a certain amount of authority for support. If the therapist is satisfied with the traditional and somewhat archaic theory that the right heart bears the brunt of pneumonia, and that death is commonly the result of failure of the right heart, his road is clear before him. It would seem, however, in the light of modern developments, that the matter is not so simple. Granting an added burden upon the right ventricle from the impeded blood flow through the consolidated lung, the diminution in capacity of the respiratory pump in promoting the return of venous blood to the heart and the probable degeneration of the myocardium from toxins or impaired oxygenation, one must also take into account the important respiratory factors. Among these are: The diminution in vital capacity, the increase in the dead space, the decreased pulmonary ventilation through rapid and shallow breathing, the presence of exudate in the bronchi and alveoli. Probably, also, the formation of methemoglobin by the pneumococcus is not unimportant. The result of these factors, with or without a diminution in minute volume flow of blood, is comparative anoxemia or oxygen unsaturation with resulting interference with tissue respiration. Conse-

quent alterations in cellular metabolism are, as yet, too subtle and complex to be measured. It would, however, seem that in oxygen unsaturation of the blood in pneumonia, as demonstrated by Stadie,¹ lies a factor more vital than failure of the right heart. The work of Meltzer² upon oxygen administration in pneumonia deserves more attention on the part of clinicians. The fact that by the insufflation method the anoxemia may be reduced is one that should be acted upon. I believe that every case showing any cyanosis or other evidence of anoxemia should have oxygen at frequent intervals from the start and not as a last resort. As Meltzer has shown that the ordinary methods of giving oxygen do not increase the oxygen tension in the alveolar air, the insufflation method or one of its effective modifications should be employed. In this connection it is appropriate to quote the following paragraph from Macleod's³ "Physiology and Biochemistry in Modern Medicine": "There is no therapeutic measure that is less efficiently put into practice than the administration of oxygen, and, as a consequence, most physicians have little faith in its value. There are several reasons for this state of affairs: In the first place, the physiological mechanism by which added oxygen could assist in the respiratory functions is not understood; in the second, an insufficient amount of the gas is usually given, and, in the third, it is usually given too late. On the other hand, when oxygen is properly administered in suitable cases before the patient has become moribund, much evidence has accumulated to show that very great benefit, indeed, results from the treatment, and as far as can be told a fatal termination is often averted."

Digitalis in moderate doses can certainly do no harm. I believe there is no convincing evidence that in the ordinary case it does much good. The fact that digitalis influences the electrocardiographic record in pneumonia is not evidence of benefit. When chronic myocardial weakness or auricular fibrillation exists, there is no question of its advantage. I confess to the use of small doses of the tincture as a routine, but without being convinced of its profit. I believe heavy doses in cases with normal hearts are unwise. In ten years I wonder if we shall be hearing so much of the use of digitalis in pneumonia.

Stimulants are a slender reed. The use of caffeine is often injudicious. A cup of strong coffee contains about three grains of caffeine. Let the therapist himself take this allowance of the drug at intervals of three hours and know the sleepless, restless, irritable state resulting. Far too often one sees the simultaneous administration of large amounts of caffeine as a stimulant and of morphine to overcome the wakefulness and irritation resulting from the caffeine. Such therapy is injudicious, if not vicious. Caffeine may be used best in the form of strong coffee, not too frequently, and only in cases inclined to be somnolent, never in the restless, agitated, sleepless types.

Strychnine seems of little avail. The diffusible stimulants—camphor and ether, whiskey, camphor in oil, etc.—are of little use. In some work done by C. C. Lieb and the writer⁴ it was shown that

these and kindred substances owed their action to strong irritation of the endings of sensory nerves and not to any direct effect on the circulation. When injected into a limb, the afferent sensory tracts of which had been severed, no change in pulse rate or blood pressure followed.

Pituitrin may be life-saving in cases with abdominal distention from toxic paresis of the gastrointestinal tube. It is best given in conjunction with a turpentine enema, and injected deeply into the muscles.

Little profit would seem to be expected from atropine. Possibly the reduction in secretion of the glands in the mucosa of the respiratory tract has a slight value in cases with too much bronchial exudate. It certainly cannot influence the transudate, which is the outstanding fact in pulmonary edema, for which it is so often used. The use of sufficient atropine to paralyze the vagus endings is surely dangerous. Simultaneous employment of digitalis—a drug that increases the activity of the vagus, and of atropine—a drug paralyzing vagus terminations, is a therapeutic contradiction which, like the concomitant use of caffeine and morphine, needs only to be mentioned.

In cases of very low blood pressure and impending collapse of the vasomotor system, adrenalin, given in small doses of three to five minims at frequent intervals, may benefit. The administration of adrenalin in oil, according to the method of Dr. H. R. Miller of New York, by which slow absorption is assured, is promising. Whenever there is a tendency toward edema of the lungs, adrenalin seems to be contraindicated.

In considering serum treatment I shall first give my impressions from various sources and then my own opinion. My first impressions are collected from rather wide sources. During 1918 and early 1919 opportunity was had of coming into contact at frequent intervals with fourteen different chiefs of medical services in as many hospitals in the Department of the Southeast. These chiefs of service were representative of the best medical opinion of varied sections of the country. The serum treatment of Type I infections was made obligatory by the Surgeon-General's Office and was carried out under the most favorable conditions with respect to promptness of typing, skilled serum administration, and recorded results. Of fourteen chiefs of service I recall but one who was enthusiastic about the serum treatment of pneumonia. None was opposed to it. The prevailing attitude toward the matter was one of inquiry. They were awaiting proof of results.

This position was borne out by statistical studies reported from the camps in the U. S. A. In a considerable series of Type I cases not treated by serum, the mortality was less than 10 per cent.; in a series treated by serum, the mortality was practically the same. Certainly the Type I pneumococcus produced mild infections among the troops in the Southeastern Department in 1918 and 1919. It is my impression that the same is true of the civilian cases observed in New York and vicinity since the war. The importance of recording further series of Type I cases to determine the average mortality rate would seem to be great.

Observations in and about New York appear to show that the use of serum is not as general as when the method was first introduced. I have heard one prominent medical consultant deplore the present lack of general interest in it. On the other hand, in one important hospital service, serum is not given in pneumonia because it is regarded as of little benefit, and even dangerous, because it appears to cause an increased number of cases of empyema, meningitis, and similar complications. I would, therefore, conclude that among the profession at large the method is still on trial.

My own opinion is that serum should be used in every case of infection with pneumococcus Type I. One cannot logically close his eyes to the experimental evidence in the matter—to both the protective and curative effect of serum in experimental pneumococcus infections in animals. Neither can one brush aside the therapeutic effect in many cases in man. When given before the third day of the disease the attack may surely be cut short in a most convincing fashion, and a stormy onset, promising a five- to nine-day struggle, eventuate in an affair of two to four days. Given after the third or fourth day, the effect, in my experience, is less striking, but not infrequently satisfactory and in serious cases worth the attempt. That some of this effect of serum in infections with pneumococcus Type I is general or non-specific is probable and is similar to the effect of injections of typhoid bacilli in acute arthritis, or of alien protein in typhoid fever. The fact that the pneumococcus Type I will grow in its own antiserum is interesting, and in the mind of the skeptic may raise doubts of the specificity of its action. The evidence derived from experiment, however, is in favor of a specific effect, and it would seem that this is to be granted.

Brilliant as is the work in establishing the serum treatment of the Type I pneumonia, I am of the opinion that the method is not destined to endure. The method is too complicated, time-consuming, and too subject to technical errors and delay to find favor with practitioners at large who are not immediately in touch with institutions equipped with adequate laboratories.

If I were allowed to prophesy, I would predict that the present method will be supplanted by one in which a concentrated solution free from the objectionable serum proteins, containing antibodies for all the recognized pathogenic types of pneumococci, and so doing away with the necessity for typing shall be developed. Happily, I am informed that very promising work is under way toward the elaboration and clinical use of such a solution.

Meanwhile, it is our duty to employ the recognized method in all Type I infections. To sum up, therefore, I would plead for

1. Less meddlesome interference with the patient, that his own resources be conserved.

2. The attention of clinicians to the factor of oxygen unsaturation of the arterial blood in pneumonia, and of the consequent importance of the administration of oxygen by an effective method.

3. The continued use of serum in Type I infections until this method is supplanted by one less

cumbersome and more universal in application.

THE COMPLICATIONS OF PNEUMONIA.*

By NELLIS B. FOSTER, M.D.

NEW YORK.

(From the Medical Clinic of Cornell Medical College at New York Hospital.)

THE complications in pneumonia may in general be assigned to three factors: First, the effects on organs of the toxin produced by the infecting agent; second, the extension of the infection to other structures than the lung; and third, secondary infections superimposed on the virus responsible for the initial pneumonia. As an example of the first class, the effects of the toxin, may be cited many of the symptoms which characterize the disease, but in addition to those which are usual it seems that at times some one organ is affected in a degree disproportionate to the intensity of the infection, due, perhaps, to vulnerability produced by latent disorder in the organ attacked. In pneumonia this condition of affairs is apt to implicate the heart muscle, and only in a certain rather narrow sense can we speak of resultant cardiac disorders as complications. Whether the disordered function resultant upon degenerations in the myocardium can be in some degree prevented by appropriate digitalis therapy still remains in dispute. But since fibrillation of the auricles is one of the disorders of function met with in pneumonia, and digitalis is definitely of use in this disorder, it may be argued that there is a general theoretical basis for the use of digitalis in pneumonia. If digitalis is used at all it must be remembered that an adequate dosage is essential in order to secure any effect whatsoever. This fact at least has been determined with something of scientific precision through the electrocardiograph.

Involvements of the pericardium are commonly examples of the second mode of origin of complications; infection by extension, through either lymphatic stream or blood. But the pericarditis of pneumonia may be due to a secondary invader, often the streptococcus. The existence of pericarditis complicating pneumonia is too frequently not recognized. Considering that the necessary examination for its detection can be made without disturbing the patient, without even changing his posture, there is scant excuse for the omission, since the presence of pericarditis is an important factor in prognosis, and a guide in interpreting

*Delivered by invitation as part of the Symposium of Pneumonia, at a meeting of the Medical Society of the County of New York, March, 1921. (See page 982.)

the significance of other complications which may arise. Fibrinous pericarditis may progress to empyema of the pericardial sac. This complication of pneumonia is usually fatal because often associated with pleural empyema. But pericardial empyema is not invariably fatal, if skilful surgical aid be available. One of my series survived and Pool has operated on a case successfully. If signs of pericarditis appear, an examination should be made daily to detect signs of fluid in the pericardium. If signs of fluid develop the question arises: Is this fluid a simple exudation or is it infected and pus? With accompanying signs of persistent infection, fever, rapid pulse, sweats, perhaps, and a general toxic appearance of the patient, it becomes necessary to know whether there is an empyema of the pericardium. This fact can be learned only by exploration with the needle. The operation in skilled hands is almost devoid of danger and nearly painless. At times this exploration, as when empyema of the pleura is suspected, is quite imperative; future treatment of the patient depends on knowledge not only of the character of the exudate but also of the infecting organisms and their relative number. The mode of treatment of empyema of the pericardium is in principle identical with that of empyema of the pleural cavity. But in order that any treatment meet with success for the patient, it is requisite that it be instituted before the patient is exhausted by the infection and his general resistance depleted.

The most common complication of pneumonia is empyema. In my civil hospital experience empyema complicated 6 per cent. of the cases of pneumonia. Empyema in my army series ran above this, due to some extent to the empyema of pneumonitis. Empyema may be due to any of the pneumococcus types, to the streptococci, either primarily or as secondary invaders, and occasionally to other organisms. The type of infection appears to influence in some degree the anatomic types of empyema. For example, empyema, due to the pneumococci, is usually circumscribed, walled off by pleural adhesions, while these adhesions form later with streptococcus empyema and may result in several separated pleural abscesses. The primary pocket may be interlobar with subsequent rupture into the pleural cavity, a clinical entity splendidly described by a former military aide, Henry M. Thomas, Jr. In civil life we see but seldom the so-called "primary empyema" complicating acute interstitial pneumonia; a rapidly developing disease wherein the signs of pneumonia are quite obscured by those of empyema. The initial symptoms of pneumonia may precede the empyema by only a few hours.

The mode of treatment of these various types of empyemata varies greatly, a fact that is now clearly understood. If empyema, due to an infection with *Streptococcus hemolyticus*, is treated in the way recognized as appropriate for a pneumococcus infection, death usually results and quickly. Not only, then, must there be early recognition of the empyema, but also it is requisite to know the nature of the infecting organism. Now two factors mainly are responsible for tardy recognition of empyema: First, an idea that empyema is accompanied by a definite type of fever curve, and

second, the notion that fluid in the pleura always gives rise to a characteristic combination of physical signs. Both of these ideas are narrow and misleading. While in many cases of pneumococcus empyema the fever does drop to normal, and subsequently rise again with the development of the pleural infection, this is not always the case, even in pneumococcus infections, and is very seldom true in infections caused by streptococci. For example, our series includes cases of Type I pneumonia with a steady high temperature caused by an extension of the pneumonia process to the other lung, while empyema developed in the side first involved. Some of these cases have recovered, due to early recognition of the empyema and its special treatment, as well as to treatment of the concurrent pneumonia.

Likewise, the physical signs are not by any means always those regarded as classical signs of fluid. Every one knows the variability of signs accompanying resolution, and when these are associated with encapsulated collections of liquid in the pleura the effect in signs is often bizarre. Implicit confidence in one's ability to interpret physical signs, unsupported by other aids in diagnosis, is doomed to receive a rude shock in the morgue. A detailed account of some of the more unusual signs accompanying empyema has been given in the *Amer. Jour. of the Medical Sciences*, 1921. The indications of empyema are not in signs alone at best, but in the evidence of a persistent infection, accompanied by signs in the chest, which might be due to a pleural abscess. The correctness of this suspicion must always be determined by exploration. Exploratory puncture is obligatory under circumstances such as I have outlined, because the character of the infection as well as the confirmation of the presence of empyema must be determined for treatment.* Empyema due to streptococcus infection is often detected by the character of the pus at once, and early aspiration and late operation constitute the procedure insuring the lowest mortality. Following the first aspiration in streptococcus empyema the fever becomes lower, sometimes a normal temperature prevails for several days, and the patient shows improvement in general appearance, increased appetite, and restful sleep. When the temperature rises again and pus reaccumulates a second aspiration is indicated. The pus at the second aspiration is usually thicker in consistency than at first, and the quantity less. This method of repeated aspirations in the treatment of streptococcus empyema has been our custom for a number of years. Two questions arise here: How long should the aspirations be continued; and what is the indication for thoracotomy? So long as the patient's condition continues to improve there is no need to resort to a change of method. Usually these patients continue to gain for ten days or two weeks when the pus becomes so thick that aspirations are not possible. Thoracotomy is then done. A minority, some 6 per

*The danger of exploration with the needle is exaggerated. Air embolism is of very rare occurrence. But even though the danger exceeded that of an operation like tonsillectomy it is well to recall that in military hospitals where exploration was much used, pneumonia mortality was lowest and unrecognized empyema at autopsy least frequent.

cent., are cured by aspiration and escape radical measures.

Now in contrast to streptococcus empyema, those due to pneumococcus infections sometimes progress most favorably if thoracotomy be done at once. Some cases may be benefited to the extent of becoming better able to endure the shock of operation if aspiration be performed at once. But seldom is a cure effected by aspiration alone, and only when the amount of pus is small.

The basic studies of Churchman in chemotherapy and particularly the application of gentian violet to wound infection may find an important field in the treatment of empyema. Waters (*Amer. Rev. Tuberculosis*, Feb. 4, 1921) has utilized with success in empyema the technic devised by Churchman for the treatment of suppurative arthritis. The principle is sound and should receive practical trial.

Pulmonary abscess is not a frequent complication of pneumonia, but it is important because of its seriousness. My reason for mentioning it is chiefly to call attention to a mode of treatment which has not been given proper consideration. Diagnosis is invariably difficult, and for correctness requires the resources of a clinic. Physical signs may be misleading when the cavity is deeply seated or thickly encapsulated, but the data gathered from observation of the sputum and the temperature excite a suspicion. The x-ray is of more help in diagnosing abscess of the lung than in empyema. The radiograph should be stereoscopic for exact localization, and when the cavity contains pus and air, information may be secured by changing the posture of the patient and noting the change in the surface line of the fluid.

The treatment of pulmonary abscess depends upon the location of the abscess. When it is near the costal surface of the lung, or near the diaphragm, there are usually pleural adhesions. When, however, the abscess is nearer the center of a lobe, such adhesions are not often found. In the latter case the lung may be collapsed by artificial pneumothorax in the same way that tuberculous cavities may be treated. The only contraindication is pleural adhesions, which of course prevent the end sought for. Some of our cases have attained a complete cure by this relatively simple procedure. Recently a patient died in the New York Hospital of chronic nephritis, who had been treated on a previous admission, some six years ago, for pulmonary abscess. The method used was artificial pneumothorax, which effected a symptomatic cure. We were not sure of the result on account of the peculiar persistent physical signs and the fact that radiographs were useless, the involved area being covered by the heart shadow. At autopsy the area of the abscess was found entirely replaced by dense fibrous tissue. The healing, in brief, had been perfect.

When adhesions frustrate attempted collapse of the lung, the only method of treatment left is excision of the involved area, or lobectomy. In the hands of a skilful surgeon, who is familiar with the peculiar problems presented, these operations should not have a mortality above 10 per cent. Pulmonary abscess does not heal spontaneously, and, when left untreated, the fate of these patients

is so distressing that a majority will risk any hazard that promises relief.

Of the many other complications which may arise in pneumonia, some are of slight relative importance, while others are almost invariably fatal, meningitis for example; therefore it seems most useful to confine this brief discussion to those lesions which are common, and for which there is a hopeful method of treatment.

121 EAST SIXTY-SECOND STREET.

DIABETIC ACIDOSIS.

BY THOMAS WEBSTER EDGAR, M.D.,
NEW YORK.

THOSE of us who have interested ourselves in the study of metabolism, especially in relation to diabetes mellitus, are confronted many times by a call from the busy general practitioner regarding his patient, who is on the border line of impending acidosis and coma. I have time and again been called into consultation on these cases at the eleventh hour, in order that I might offer some suggestions or means to snatch the patient from the terrors of intoxication.

To the general practitioner who is treating an occasional case of diabetes, it is of paramount importance that he realize the following two axioms: First, that sooner or later his patient is prone to develop an excess of the lower fatty acids, with a resultant acidosis, and secondly, if the condition is not immediately checked, only very heroic means will save the patient.

In my association with the general practitioner I have found that too much stress has and is being placed on the sugar content of the urine and that a great percentage of the therapeutic measures adapted are solely for its rapid reduction, other symptoms and conditions all being neglected. It seems to be the popular hypothesis, or I may say conception, that as the urine sugar is minimized, so the other manifestations of deranged metabolism are lessened or overcome. At times, and in selected cases this is true, but in the great majority of patients it is not. By the great majority I mean the ordinary moderately severe case running a 2 per cent. urine. Oftentimes these cases do not feel as energetic when the sugar is reduced, as they did when passing urine with a higher content of sugar.

The management of diabetes is much like that of interstitial nephritis. Both conditions are progressively chronic. During the life time of the individual we should strive to keep them economically fit. Many times the diabetic patient is prone to change his or her physician. Each new medical advisor immediately begins a period of starvation. He treats these patients en masse and not individually. Some respond, while the great majority do not. The hyperglycemia and glycosuria are minimized, yes, but the subsequent symptoms dependent on carbohydrate starvation soon make their appearance and the patients are pitiful to behold. They are sugar free, but prognostically and economically they are worse off after each starvation period.

Unfortunately we are living in the starvation era in the treatment of diabetes, in that it is applied

too harshly in the great majority of cases. The physician does not appreciate existing conditions of metabolism in his patient. I have seen diabetic patients suddenly collapse under this form of treatment when applied by an over zealous medical man in his endeavor to lower the sugar. In a former paper entitled "The Limitation of Starvation in the Treatment of Diabetes" I endeavored to point out the necessary selection of cases when starvation is to be applied and stated that its institution is a dangerous procedure unless existing conditions in the patient are thoroughly appreciated and treatment applied by one skilled in metabolic work, having at his beck and call modern equipment for the estimation of the various excretions and secretions.

Because an individual has diabetes mellitus, it does not signify that starvation is going to produce the best result. Other therapeutic measures may offer far better results. It does mean, however, that he should be placed in the best possible condition and kept there. By best possible condition I refer to both physical and economic conditions, the latter being of paramount importance both to the individual and to those dependent on him. His prognostic rating should be immediately taken into consideration and his assimilatory mechanism afforded the necessary heat and energy to carry him along in a manner that does not rob the body of vitality and resistance to overcome the obstacles that a diabetic finds scattered in his path. The disease itself is a malady of sugar starvation, and in the majority the withdrawal of carbohydrate is contraindicated in spite of many beliefs to the contrary.

The more one sees the frequently starved diabetic the more one appreciates these facts. Undernutrition (and undernutrition must accompany starvation if it be effective) is the stone of calamity in the lives of many diabetics, and from this point many individuals, although sugar free, progressively go down hill.

It is plausible to believe that in order to insure carbohydrate metabolism a larger amount of sugar in the blood is required, and any radical artificial reduction of the glycemia below this point must be attended with manifestations of disturbed carbohydrate metabolism.

Glycemia and hyperglycemia must not be reckoned with while other manifestations are utterly neglected. Many patients are worse off with a sugar free urine than others whose sugar content is high. I have frequently seen the sugar free diabetic display a greater tendency to intercurrent infections and gangrenous processes than patients who were both markedly hyperglycemic and glycosuric.

If diabetes is a symptom which is the result of a functional inability of the pancreas to secrete a full amount of its internal secretion, then I doubt very much whether the withdrawal of its normal activator (carbohydrate) is indicated. In other words, glandular activity ceases when the specific stimuli are removed in part or whole. This is best portrayed by the fact that the simple act of starvation in the normal person will produce a glycosuria. If an organ or group of organs are not called upon to exert their full influence on

some form of resistance, they will atrophy and in the course of time become rudimentary and inert, and I fully believe this is what takes place in the diabetic who is subjected to prolonged withdrawal of carbohydrate.

The logical termination of diabetes should be considered acidosis and coma. When a case is first seen, no matter how mild the diabetes may be, this issue should be given consideration. One author of my acquaintance states that if a patient succumbs to acidosis, it clearly shows that he has received poor treatment. In view of the fact that my confrère is a member of the starvation school, I feel that he should have qualified his remark, as these patients rarely survive to reach a terminal acidosis. Then, again, he is seeing practically all his patients at an institution, where they remain for only a short term of treatment. This issue may better be argued by the general practitioner who has the diabetic under his constant supervision for months and even years.

As the body slowly loses its power to assimilate and warehouse its carbohydrates, heat and energy so necessary to the maintenance of life must be manufactured from body tissue. The surplus fat is now called upon, as a result of decreased resistance, oxidation is incomplete, the lower fatty acids, especially beta-oxybutyric acid, accumulate in the blood, concentration slowly takes place and coma supervenes. By instituting starvation in many cases an active ketonuria is set up, first because the fat-sparing food stuff is denied the body, secondly, because the body tissue is incompletely oxidized with the production of the lower fatty acids.

Thus as the logical termination of diabetes is acidosis, how are we to manage these patients whose tolerance is nil and who are slowly but surely ascending the ladder of ketonuria. When called upon to see such a patient I immediately institute a routine form of treatment that has been most successful in not only neutralizing the acid formed, but in minimizing its further production.

If the patient is not in coma and is able to take food by mouth I immediately introduce into the stomach one gram of carbohydrate per kilogram of body weight in the form of orange juice or oatmeal gruel. This is best divided into four doses, and administered during the twenty-four hours. In these cases the introduction of fluid is essential. My method is to see that the patient takes by mouth at least three thousand cubic centimeters of either warm water, tea, or coffee in the twenty-four hours. A high colonic irrigation is given, consisting of one dram of sodium bicarbonate to the quart of water. This is repeated daily till symptoms of acid poisoning have been conquered. No other food should be allowed during this treatment. If the patient presents evidence of great fatigue, poor, thready pulse alcohol should be administered well diluted, an adult taking as much as four ounces during the course of the day.

In those patients who are in a semicomatose condition, nauseated and dyspnoic, I immediately introduce high up into the colon six ounces of the following: Glucose 5 per cent., sodium bicar-

bonate, 2 per cent., dissolved in six ounces of saline solution. If the patient is a large individual I increase this to eight ounces. This to be retained. If conditions are such that active stimulation is necessary one ounce of whiskey may be added.

To maintain arterial tension 500 to 1,000 c.c. of sterile physiological saline solution is introduced into the median basilic vein. The quantity necessary depending, of course, on the age and size of the patient. In the severe type where very heroic measures must be adopted, I infuse with a 2 per cent. glucose solution to which nine-tenths per cent. sodium bicarbonate is added. This procedure is repeated the next day if necessary.

In patients suffering from an accumulation of betaoxybutyric acid, fluid depletion of body is evident, accompanied with great loss of weight. Incidentally it may be stated that the body alkali reserve is exhausted or nearly so: which is the natural course of events in that the body has been called upon to neutralize the acid formed. Thus the indication is apparent to renew or introduce sufficient quantity of a base to bring back or renew pre-acidic alkalinity.

Many followers of the starvation theory do not believe that sodium bicarbonate is capable of influencing the acid condition. I feel that their opinions have been too hurriedly arrived at, as a result of the administration of either too large a quantity or not enough. To substantiate my observations I offer the following as a theoretical explanation of its action.

There is no question that the neutrality of the blood is maintained by an equilibrium established by the salts of the blood. The blood possesses the property of being able to take up considerable quantities of acid without appreciable change in the hydrogen-ion concentration. The plasma contains sodium bicarbonate. The normal ratio of carbonic acid to sodium bicarbonate is one to twenty. When acid is added it reacts with the bicarbonate to form a salt and carbonic acid. The hydrogen-ion concentration resulting will not increase in proportion to the amount added in the acid for the reason that carbonic acid is but slightly dissociated, but the slight increase is promptly removed by the lungs as carbon dioxide, the removal of carbon dioxide permitting the hydrogen to react with the remaining atom of oxygen to form water and again restore the one to twenty ratio of carbonic acid and sodium bicarbonate. When sodium bicarbonate is no longer sufficient in amount to maintain the neutrality, in case of continued addition of acid, the phosphates enter the reaction. If this mechanism is insufficient there may be an altered nitrogen metabolism and ammonia is diverted from the neutralization of acid and excreted in the urine. So long as the one to twenty ratio is maintained the acidosis is compensated. Here the absolute value of the alkali may be diminished. Only when the ratio is altered is it uncompensated.

From the above it is plausible to assume that sodium bicarbonate does act as a neutralizing agent. An effort should be made to bring the alkali reserve to its normal value, but never to exceed it.

Digressing slightly I may mention the fact that it has always been my belief that body weight should be preserved, and not sacrificed, as is the belief of the starvation school, unless, of course, the patient is obese. I have through experience found that the patient who has a fair reserve of body tissue is more slow in developing an excess of acid than one who is thin and cachectic. This reserve supply of tissue may be considered in terms of acid resistance, which stands in good stead during an emergency. In the past a normal excess of body fat has been considered as so much excess luggage, and the advocates of starvation have endeavored to remove it, with the idea that fat limits oxidation. As starvation must be accompanied by undernutrition to produce results, body weight is sacrificed by advocates of this system. As a result their patients are always under weight, undernourished, and underfed. I have never in my experience seen the diabetic patient who has been able to retrieve his previous body weight and resistance after undergoing a series of fasts. Body weight is the one reliable gauge we possess as to the progress of the patient, except, of course, aside from any dropsical condition that may be present.

A diabetic who is constantly losing weight, regardless of his sugar content, is going down hill and nearing the point where some slight change in diet or mode of living will invoke an increase in the acid. I have never seen a patient who was gaining or maintaining his weight go into coma. Impending ketonuria is always preceded and accompanied by great loss of weight. During actual coma this loss is greatly augmented by the splitting of the fat molecule. Thus 210 grams of fat will yield 72 grams of betaoxybutyric acid, while from 120 grams of protein, 36 grams of oxybutyric acid may be formed. As acidosis is the direct result of products formed from the incomplete oxidation of fats, plus a depletion of the alkali reserve, it becomes necessary to limit the elements and substitute that which will spare fat, as well as introduce a substance that will increase the alkali reserve.

Just how much beta-oxybutyric acid is necessary to produce coma is dependent on several factors, foremost of these being the age of the patient. Children are able to withstand acid intoxication much better than adults. Dehydration or depletion of body fluid invites ketonuria. The alkali which I have mentioned, stored in the body as potassium, sodium, calcium, and magnesium, acts during impending acidosis, by changing the path of excretion from bowels to kidney, in order that oxybutyric acid may be removed or eliminated. Much, however, depends on the cardio-renal system for the rapid and effective excretion of these bodies in order that concentration and accumulation do not take place.

756 WEST END AVENUE

No General Predisposition to Cancer.—Fibiger, the wellknown cancer student, states that the white mouse seems almost immune to cancer as generated by the *Spiroptera*, the nematode worm with which he has worked for many years, but it is unduly susceptible to tar cancer. Facts like these militate against the hypothesis of general susceptibility and general immunity to cancer.—*La Presse Médicale*.

BLOOD IRRITANTS OF DIETARY ORIGIN.

By J. M. W. KITCHEN, M.D., M.S.

EAST ORANGE, N. J.

PRESUMABLY all who have given much study to the subject will agree that diet has a very large influence in determining the nature of all animals; and in man, the production of disease and the return to normal states; but it is doubtful if we fully realize the power of that influence. Most physicians in cases of sudden attacks of sickness, involving bedside attendance, will advise a suitable diet; but in case of chronic or semichronic conditions, they are very likely to prescribe such diets as are indulged in by themselves without obviously injurious effects. Nevertheless, it is probable that substantially all individuals of the race who can control the wherewithal to indulge their gustatory desires, are more or less victims of gustatory vice.

I have had an excellent opportunity to observe the effects of various dietary indulgences on my left knee for about three years; and it may be of general interest if I record some of my latest conclusions in this connection. My trouble started with a knee strain augmented by neglecting to give it immediate rest; and finally, when I retired to bed with it, by not cutting down my diet to meet the bed-ridden condition. The result was a brisk generalized rheumatic attack and more or less localized trouble in the knee ever since, most of which has been due to lack of will power to restrict my diet sufficiently to meet the needs of the case. I love the pleasures of the table as well as other people. My knee is better, and I can eat things now with moderation that would have been entirely out of the question a year or more back; an allowed indulgence which I attribute to a development of a considerable amount of fibroid tissue at the affected point, with a consequent acquired greater resistance in character of the affected joint to blood irritants.

In this writing, I use the term "irritants" as applied to blood conditions that are obviously damaging to non-resistant bodily tissues, and which also cause damage without concurrent objective or subjective recognition that damage is being produced. I quite agree with those who think that most of us eat too great a quantity of food, and that such indulgence in quantity may be more at fault than errors as to quality in the food supply. It is clear that various individuals, and entire peoples, become more or less adjusted to the character of the food they have habitually consumed. But this does not say that every diet is equally good. The meat eater may, with his relatives of carnivorous habits of the lower orders of life, get on for a certain length of time comfortably, as may also the Esquimaux and the denizens of the tropics exist with their peculiar diets, as well as the nonsensical habitués of the nicotine, alcohol, and caffeine addictions.

We must take into consideration the fact that with the development of man's brain, many avenues have been opened to the reception of pleasurable indulgences. Unfortunately, there has as yet not been a sufficient development of a counteracting influence of control of our desires the repression of which is of importance to our best interests.

The pediatricists are still struggling with the problems of how to treat cow's milk for infantile

diet through modifications; and I am sorry to say they are as yet, along with other practitioners, apparently ignorant that the public supplies of milk, cream, and butter are all without exception more or less contaminated with the products of putrefactive fermentations; that moderate protective heating of clean milk does not produce scurvy in babies; and that, imagination to the contrary notwithstanding, the exhibition of a little orange juice would certainly make good any loss of the elusive vitamins in milk. Also, so far as the world at large is concerned, it apparently does not realize that the dietary habits of a lifetime will usually result in the distention of the stomach, and an acquired consequent hunger that can ordinarily be alleviated only by filling up that viscus. That is only one of the unacquired scientific facts, a recital of which, if printed, would form a library of considerable size.

My previous articles related to this subject have been followed by a kindly extension to me individually, by medical confreres, of special information which has resulted in my having become somewhat of a repository of special pertinent knowledge, and in my having arrived at conclusions that I had not before formed. Some of these seem to offer reasonable explanation and hypothetic views of many related points that are at least new to me. Of course, in theorizing as to the mechanisms going on in our wonderful bodies, imagination may lead to inaccurate conclusions; but it is at least a comfort to feel that we have arrived at somewhat acceptable theories more or less sound.

My basic conclusion is that the bodily tissues may be more or less entirely resistant to most of the irritants in the blood that cause a large number of abnormal conditions; and conversely, all or part of the tissues may be weakened in their resisting power to such irritants. Among the conditions determining this matter of resistance are: age, previous disease, special wear and tear, the nature of occupation, climate, etc., all of which, along with others, including traumatisms, conduce to the non-resistant status. I think we must all acknowledge that the absorption of decomposition and fermentative putrefactive products is highly noxious. I wish I could form some satisfactory theory as to the mechanism in the body of the action of the putrefactive poisons; but we are largely restricted in forming our opinions, by the symptoms produced by these poisons; as is the fact in the case of many other poisons to which great study has been given.

The conclusion is easy to accept that hyperacidity in the blood is a cause of irritation. I have been astonished to note how small an amount of ingested meat will be followed by a pain in my knee. There appears to be no question that meats develop acid end-products found in the blood. The conditions producing acidosis are frequently a cause of irritation.

There is no longer any question in my mind that accumulated sugar in the blood is an irritant. I have not found any explanation as to what becomes of the large amounts of sugar that we consume; but it is certain that sugar may be found in the blood that is not accounted for in the urine. I believe the race is being seriously damaged by an extraordinarily large consumption of sugar. Possibly some day the uncontrolled sale of sugar will be prohibited for hygienic reasons.

The accumulation of irritating non-eliminated products of metabolism is evidently continually at work in adding to the miseries of man; this situation being greatly aggravated by the artificial nature of modern life, including the use of the automobile and general neglect in taking effective exercise. The requirement of most individuals having to work vigorously with the muscular system, will prevent a complete race suicide resulting from sedentary life; but the fullest enjoyment of healthful states can only be expected when adequate exercise of all of the tissue of the body is habitually practised.

Plethora of nutritive constituents in the blood must be considered as irritating, even if the food supply is well balanced as to alkaline constituents. The mere fact of condensation of nutrient matters must exert an influence on non-resistant tissues, in the mere physical osmotic interchanges between the blood contents and the cellular contents. The direct action of germs on irritated tissues I am not considering in this connection. I think it is a rare condition of irritation as compared with those of dietary origin. I feel very certain that irritants of the character already cited may have a special influence in causing a host of abnormal conditions, whether rheumatic, dermal, biliary, renal, or nervous; and also, a considerable list of hyperplasias, such as goiter, glaucoma, and even cancer. If we add to such direct irritations, the influences of hypertrophic conditions of the nerve centers more or less continually sending blood and nerve stimuli to affected parts, do we not have a reasonable hypothesis as to the causative factors of many troubles that at present are not generally accepted?

In my own case I have found that everything that will throw an unusual amount of work on the gastric mucosa, will cause pain in my knee. This I think, is due to a larger production of gastric acids than can be neutralized by the alkaline juices further along in the alimentary tract. I doubt, even if much sugar is not eaten, that a considerable excess of starch that is not turned into glucose and absorbed as such, will furnish large amounts of food for the intestinal acid-forming bacteria; but excessive gastric acids and acids formed in the intestines, will explain the irritations of hyperacidity of the blood.

Of those articles of consumption that I have found especially objectionable in connection with gastric irritation, I cite in order of their decrease in noxious character: maple syrup; grape fruit; tomatoes concentrated in cooking, especially in iron utensils; concentrated sugar confections; curried concoctions, mayonnaise dressing; salted and smoked meats; poultry; oily fish; cooked oyster eyes; anything inadequately comminuted, or that is of such texture as will prevent easy and quick entrance of the gastric juice to all parts of the ingested mass. Large amounts of starchy matters seem to be objectionable; though recent experience in feeding babies would indicate that if the starches are thoroughly boiled in milk, the objection of large clots forming is overcome; and I cannot see why large amounts of dextrinized, hydrated starch should not be carried entirely through the alimentary tract without producing objectionable results. I have not experienced any trouble from ingested milk; probably because of its good alkaline content. My esteemed younger confrere, Dr. Miner C. Hill, informs me that in his

experience in feeding dried milk, which of course has been highly heated and its vitamins probably driven off, he has not seen resulting scurvy, even if orange juice is omitted. One must remember that in bringing milk in contact with a highly heated roll, practically all putrefactive volatile matters are driven off. Apparently the great trouble in connection with dried milk as a food is securing milk that has not been seriously infected, or its infections increased before the drying process. Of course, the fine dried particles do not digest so quickly, but they pass out of the stomach more readily in fluid menstrua, and if not completely digested in the stomach, would probably not undergo much putrefactive fermentation in the intestine, because such milk would have unquestionably all of its putrefactive infections destroyed by the high heat employed. The great trouble of quick rancidity in dried whole milk can be overcome by packing the product in small cans and dating the cans with the date of production. I have not found any trouble in eating very considerable amounts of good quality butter, so far as constitutional irritation is concerned; but I am suspicious of rancid fats, though I am not able to submit any theory for my prejudice. Raw fruits I view with suspicion, especially strawberries. Most of the vegetables are apparently unobjectionable, excepting egg plant and cucumbers. Cabbage I do not despise. Idiosyncrasy, of course, must always be considered with this matter of foods producing blood irritants.

The greatest enemy of civilized man is the accomplished chef with his innumerable allurements; but plain living conduces to the welfare of every man.

If I extol one article of food above others, it is the low cost oat, which is the best and lowest priced of all foods. It contains lime in large quantity, and has an admirable balance of food principles. But even the oat may be a poison if not properly prepared. Cooked into an adhesive gluey mass and ingested in that form, it disorders the stomach and induces a constitutional poisoning. But if prepared without settling free the contained starch from the encasing cellulose coating; if precooked and with the grain form retained, and merely eating with a considerable amount of warm water, but without milk and sugar, this food is a salvator of men of all ages and specially of men advanced in life. If it is consumed in adequate amounts as a first course at every meal, it acts as a relatively harmless gastric stuffing, to which a considerable amount of indulgence in other foods more pleasing to the gustatory sense, can be added, and along with the other foods it finds its way to the outer world without having given up too much of its starch contents, and having incidentally, through its bulk, prevented intestinal static conditions.

In further prevention of intestinal stasis, I urge eating a bran cake that I think I should receive credit for having originated. Graves desired as an epitaph, that he "fed fevers." But I am sure that if the sedentary world should all make use of my bran cake, there would be a very large monument erected to the memory of some one whom modesty prevents me from naming. Its preparation follows:

R 4 cups of clean wheat bran,
1 cup wheat flour,
Sodium chloride,
Sodium bicarbonate, q. s. My cook knows.

Mix vigorously. Beat up one egg with warm water and thoroughly moisten the dry constituents. Spread out to one-half inch thick in a metal pan, cover with a tin plate and bake. Eat with considerable butter that has been pasteurized. It tastes good and acts well. It seems almost absurd to point out that the world needs to acquire a knowledge of the simple facts that we eat too much, that we should cut down meats to a considerable degree, cut out sweets, and avoid foods or methods of eating that are not conducive to quick and painless digestion. Yet lack of that special knowledge is a matter of such importance that the life of most members of the race is largely shortened, and incomputable, aggregate unhappiness is inflicted through ignorance of the facts, and perhaps through inadequate will power to repress appetite for the pleasures of the table.

Perhaps I should add that tea, coffee, cocoa, alcohol, tobacco, and any of a number of stimulating matters in the way of sauces and flavoring compositions, should justly be considered as being, directly or indirectly, sources of blood irritants. I will even admit that excessive composition of sodium chloride may be damaging. Nevertheless, we must not forget that a reasonable indulgence of our gustatory desires conduces to our happiness, and, hence, bodily welfare. I am down on the "hip pocket" flask; but hesitate to come out radically advocating entire abolition of the pleasures of "eats."

"Let us eat, drink, and be merry, for to-morrow we die." Probably the originator of that quoted philosophy had in mind the merriment caused by the primary stage of alcoholic narcosis; but I have never been able to observe the "merry" stage to extend beyond the last stage of any ordinary feast. We always pay the next day for our indulgence, and sometimes pay heavily. Why should we die "to-morrow"? Why not live on to one hundred, plus? I have arrived at the time of life when the time of the "to-morrow" passing is only a little way ahead at the best; and yet I do not want to die before I have convinced the world that some peculiar conclusion I have arrived at in regard to "eats" and "drinks" are sound, even if they may not seem so to many.

Houdini, the "Self-Liberator," states in "Fragments" that he keeps himself fit to do his stage stunt work, because he doesn't drink, smoke, or dissipate; and that he swims and walks in the way he should, so that he is ever steel-like, supple and pliable. I know I am prolonging my life, because I am moderately temperate in many things, and hence I largely give up my inherent desires to indulge in many pleasures that my flesh craves; and only have ambition to prolong my life.

Who is morally responsible for the overwhelming influences that dominate human life? "Death comes to all," said brave Horatius. Accidents may precipitate the passing, and accident may come from outside environment, or by contributory neglect to look all ways before crossing traffic lines. The sins of our ancestor have much to do with our life's span. But it seems that the reason that we die as soon as we do is largely owing to ignorance as to the simple dictates of sensible habits of life. There is a suggested thought from some philanthropic reformative genius.

94 PROSPECT STREET.

A CONCEPT OF X-RAY PATHOLOGY.

XIV. NEPHROPATHY.

By A. J. PACINI, M.D.,

WASHINGTON, D. C.

CHIEF OF LABORATORY AND X-RAY SECTION, HOSPITAL DIVISION,
U. S. PUBLIC HEALTH SERVICE.

UNDER the title of nephropathy it will be expedient to consider diseases of the kidneys and diseases of the extrarenal urinary passages, including the ureters and urinary bladder.

The nephropathies may be studied in groups under the following heads: (Barker)

- I. The Congenital Nephropathies;
- II. The Nephropathies of Circulatory Origin;
- III. The Toxic Degenerative Nephropathies, or the Nephroses;
- IV. The True Inflammatory Nephropathies, or the Nephritides;
- V. The Nephropathies associated with Diseases of the Renal Pelvis;
- VI. The Parasitic Nephropathies; and
- VII. The Neoplastic Nephropathies.

Technique Involved.—In the study of the urogenital tract it is important that the roentgenologist exercise particular effort to secure plates of maximum utility. It is here that the competence of the x-rayist is fully tested; for while many thrive to obtain plates of much photographic beauty, few appear to realize that the softness of the renal tissue and the similarity of its density to adjacent structure is so great, that to obtain photographic contrast means to lose pathological acuity. The preparation of the patient is important and every effort should be directed to eliminate gas accumulation in the overlying intestine. This is best accomplished by the administration of vegetable cathartics the night before the examination and frequent enemas on the morning of the examination until it is certain that the bowel is emptied.* No food should be permitted. The patient should be immobilized during the exposure by compressive pressure on the abdomen, which pressure serves also to displace the gut. In creating the pressure a loofa sponge or a distended basketball bladder should be interposed between the Hickey cone and the abdomen.

The kidney is displaced one-half inch during the respiratory excursion so that the patient should not be permitted to breathe during the exposure. The centering point for each kidney is two inches from the middle line midway between the xiphoid and

* (From the U. S. Army X-Ray Manual): "To obtain satisfactory results it is necessary to eliminate confusing shadows of substances found in the gastrointestinal tract and to get rid of accumulations of gas in the colon which tend to obscure the kidney shadows and may obliterate small calculi. For that reason it is a condition precedent to every examination of the urinary tract to prepare the patient by thorough catharsis. Castor oil, about 1½-2 ounces for an adult, is the best cathartic for this purpose, as it helps to eliminate gas. If, for a good and sufficient reason, it cannot be used, a large dose of one of the other vegetable cathartics may be given. The metallic substances, in particular calomel, should never be used, because they have a tendency to produce gas.

"The cathartic should be administered the evening before the examination, the patient abstaining from all food in the interval. For that reason it is best to make these examinations in the morning, omitting

the umbilicus. The following is from *Hirsch's "Principles and Practice of Roentgenological Technique"*:

Urinary Tract.—Essential Features: Tenth, eleventh and twelfth ribs; psoas muscles; transverse processes; kidney outlines. Difficulties: Intestinal contents obscure structural outlines, hence preparation necessary. Vegetable cathartic the night before and enemas the next morning until bowels empty. No food before examination. Urates of soda calculi, cast no appreciable shadow. Extraureteral or renal shadows simulate those of calculi, hence catheterization and injection of contrast media sometimes necessary—collargol 10 per cent., thorium. Immobilization of kidneys must be accomplished by pressure on abdomen, which also displaces gut. Kidneys move $\frac{1}{2}$ inch in respiration.

Exposures: Upper urinary tract—dorsoventral; lower urinary tract—dorsoventral; ventralsdorsal, supine or prone.

Kidneys and Upper Ureters.—Posture: Ventralsdorsal—supine—shoulders elevated, knees flexed. If the individual kidneys are to be examined, 8 x 10 plate is placed under the lumbar region so that one-half the plate is below last rib. The upper ureter is then examined by a second 8 x 10 plate so placed that its upper edge is two inches above highest point of iliac crest and its inner edge in mid-line. If 10 x 12 plate is used it is placed broadwise, the lower border of the plate being at a plane through the umbilicus.

Immobilization: Compression of upper abdomen (a) (1) inflated rubber ball (preferred), (2) Loofa sponge, (3) aluminum bowl, (4) canvas band; (b) voluntary—cessation of respiratory movements.

Tube Position: For single kidneys, five inch cone under anterior ribs inclined 30 degrees cephalward. For both kidneys and upper ureters eight inch cone with ball under lower ribs, inclined ten degrees.

Lower Ureters and Bladder.—Posture: Ventralsdorsal—knees elevated. Plate (10 x 12) with lower edge one inch below gluteal fold. If individual ureters are examined the lower edge of the plate (8 x 10) is just below gluteal fold.

Immobilization: As above.

Tube Position: Eight inch cone, lower edge over symphysis; incline ten degrees downward; for single ureter—five inch cone. For both ureters—upper edge 5 inch cone $1\frac{1}{2}$ inch above umbilicus.

Bladder.—Posture: Dorsosventral—body prone, incline block 23 degrees under lower abdomen so as to raise pelvis.

Immobilization: Cessation of respiration.

Tube Position: Five inch cone; lower edge, at tip of coccyx. The prone position for kidney examination is utilized in the fluoroscopic examination of the urinary tract.

Kidneys and Upper Ureters.—Posture: Prone—on canvas topped table, on inflated spherical rubber ball 6 inches in diameter placed between lower ribs and crests of iliac. Arms over edge of table. Plate on back—held in position by sandbag.

Immobilization: Pressure of body on ball. Cessation of respiration.

breakfast, but allowing the patient to take a little coffee or tea. If the examination is made later in the day the patient might have to starve too long.

"An enema if properly administered, would be of assistance. Experience, however, teaches that it is very difficult to have it done properly, and for that reason it should be avoided as a routine measure. In those cases, however, where the administration of catharsis is contraindicated or time does not permit it, a low soap suds enema may be given an hour before the examination, the tube being retained in the rectum for half an hour to facilitate the escape of gas.

"If it can be avoided, the patient should not be examined during or immediately following an attack of colic. During an attack he is usually too sick for such an examination. Besides, at that time and immediately after, he is invariably under the influence of an opiate or similar drug which interferes with efficient catharsis and almost always causes the accumulation of gas in the colon."

Tube Position: Underneath table. Focal point just above umbilicus.

Lower Ureters and Bladder—Posture: As above.

Immobilization: As above.

Tube Position: Central ray $2\frac{1}{2}$ inches above symphysis.

Says the U. S. Army X-Ray Manual:

Technique.—Several observers, notably Shenton and Manages, have advocated fluoroscopy in the examination of the urinary tract. While in the hands of careful and exceptionally skillful operators this method is of value, yet in the hands of the average operator radiography yields the best results. Therefore this article is based entirely upon the radiographic method.

The most common method employed in the examination of the urinary tract is the one in which the patient is in the recumbent position, the tube placed above, the plate below. Most roentgenologists use, in addition to the plain diaphragm, the compression cylinder or cone. Some operators, however, use merely the diaphragm, and others, notably Caldwell, place the patient in the prone position, the tube below the table and the plate above the patient at the back. Placing a rubber bag filled with air under the patient, his weight will produce the necessary compression in this position. Inasmuch as the base hospital tables used in the army are arranged for work with the tube above, the technique best adapted for these tables will be described here. There are many variations in the technique employed. When a small cylinder or cone is used it is necessary to make five exposures to cover the urinary tract, namely, one for each kidney, and the upper third of each ureter, one for the middle portion of each ureter, and the fifth for the lower third of both ureters and for the bladder. Others, by using a slightly larger cylinder, make only four exposures, including the middle third of both ureters, on one plate. The writer prefers to use a cylinder $8\frac{1}{2}$ inches in diameter, which enables him in the majority of cases to make one exposure (or set of stereoscopic exposures) for the upper half, and another for the lower half of the urinary tract. This technique is sometimes modified to suit individual cases. If the patient is very stout, it is necessary to make special exposures over individual kidney regions. Similarly, special exposures are made over regions which are particularly under suspicion or for which a confirmatory examination is desired.

In older men and in all cases where concretions in the prostate are suspected, an examination of the bladder region should be made in the dorsoventral position. In this exposure the tube should be tilted slightly upwards and centered as nearly as possible on the sacrococcygeal junction.

In all cases the entire urinary tract should be examined no matter whether the symptoms point to a definite region or not. Only by observing this rule will mistakes in a diagnosis be avoided. For, in a great number of instances, the calculus may be found on the side opposite to that indicated by the symptoms. An examination of a single area is permissible only when it is done for verification.

In making the examination with the cylinder, it is advisable to tilt it upwards for the upper half and downwards for the lower half. The operators who are examining individual areas with the smaller cylinders or cone as a rule try to get the upper rim of the cylinder under the free border of the ribs. (The term upper and lower are made with reference to the patient, the upper referring to cephalic, the lower to caudal end.) The advantage obtained by getting the cylinder or cone under the ribs is that calcifications in the costal cartilages are not projected upon the kidney shadows, and thus confusion is avoided.

The beginner will soon learn which are the best angles for the apparatus he is using. As a guide he should use the accompanying illustrations until he has acquired his technique.

Various devices are employed in order to prevent the abdominal wall from protruding into the opening of the cone. One of these is the attachment of an aluminum hemisphere to the lower opening of the cone. Another is to place between the cylinder or cone and the patient's abdomen a rubber bag filled with air or a pad made of loofah sponges, or absorbent cotton.

These must be wider than the rim of the cylinder or cone and of ample thickness. They should be tested by radiography or fluoroscopy to ascertain that they are free from shadow-casting substances.

Quality of Tube.—It is best to use a tube of fairly low gap, about 3 to 4 inches (using a slightly lower gap perhaps for the Coolidge than for the gas tube) at 40 ma. or more. The length of exposure depends upon the speed of the plate and the current used. It may vary from 2 to 6 and be as long as 10 and 15 seconds. Great rapidity is not needed, if the parts can be properly immobilized and the patient can be made to hold his breath during the exposures over the upper half of the urinary tract. Complete arrest of respiration holds the diaphragm still and the kidneys at rest, enabling the operator to obtain good kidney outlines.

Position.—It is very important to have the spine straightened out, so that it completely touches the plate. In those instances (and they are many) where the patient's back is so curved that the simple recumbent position will not straighten it sufficiently, his shoulders may have to be raised and the hips and knees flexed. When doing the latter, one must be careful not to bring the tube terminals too near the knees. If that cannot be prevented, a good heavy insulator ought to be interposed, and if that is not feasible, one had better allow the back to remain curved.

Clothing or bandages in the path of the rays between the target and the plate should be avoided. In case the removal of bandages is not permissible correct information as to what is hidden by them must be obtained before stating definitely that a certain shadow is a calculus. It is well to remember that dried blood or pus in a bandage or dressing will cast a shadow.

Quality of the Plate.—The greatest difficulty in this examination is encountered when no calculus is seen on the plate. The question then arises, is the plate good enough to make a negative diagnosis with absolute certainty? Credit is due to the late Charles Lester Leonard of Philadelphia for having laid down the rules which with but one addition hold good to-day. These rules are: A plate to be considered as having the necessary radiographic quality must show at least the eleventh and twelfth ribs, the transverse processes of the lumbar vertebrae, and the edge of the psoas muscle. The only addition to Leonard's rule is that at the present day one must also demonstrate the kidneys. In the days of Leonard the x-ray technique had not been developed sufficiently to enable us to obtain kidney shadows in all cases. Even to-day it is sometimes difficult to live up to this rule. The right kidney is frequently obscured by the presence of gas at the hepatic flexure. But when on a plate showing both sides of the upper half of the urinary tract, one kidney is clearly shown, we may accept the plate as of good quality, though it does not show both kidneys clearly. Another point to remember is that great contrast between the spine and pelvis on the one hand, and the soft tissues on the other, is not desirable. Such a plate presupposes an overexposure with a tube of low penetration in which a small calculus may be obliterated.

Congenital Nephropathies.—These include malformations of the kidney which Newman has conveniently classified as follows:

"A. *Displacements of the kidney without mobility.* (1) Congenital displacement without deformity. (2) Congenital displacement with deformity. (3) Acquired displacements.

"B. *Malformations of the kidney.* (1) Variations in number, including (a) supernumerary kidney; (b) single kidney, due either to congenital absence of one kidney or atrophy of one organ; and (c) absence of both kidneys. (2) Variations in form and size, including (a) general variations in form, lobulation, etc.; (b) hypertrophy of one kidney; and (c) fusion of two kidneys, as in the horseshoe kidney, the sigmoid kidney and the disk kidney. (3) Variations in the renal pelvis, the ureters and the renal blood vessels."

Of great importance to the clinician, under this head, are movable kidneys and cystic kidneys. For determination of the position of the kidneys it is found sufficient to expose a large plate which includes the right and the left side, and to compare the shadows, making every allowance for the anatomical difference in the level of the kidneys. For a study of variations in the form and size of the kidney a similar exposure may sometimes suffice. When malformations are to be studied resort must be had to pyelography, by means of which injection the position of the renal pelvis may be gauged.

Nephropathies of Circulatory Origin.—In these there is included chronic, passive, congestion of the kidney, diffuse sclerotic nephropathy, and senile Ziegler form of renal disease. In all, the radiolucency of the kidney is increased; but the x-ray evidence may not be great. Of the inflammatory nephropathies there is no x-ray evidence, excepting occasionally in special forms of specific inflammation. Tuberculosis of the kidney occurs in two forms: (1) a miliary tuberculosis of the kidneys, which is merely part of a general miliary tuberculosis; and (2) an extensive local renal tuberculosis, in which the tuberculous process is not general through the body, but may be mainly confined to the urogenital apparatus. Clinically, miliary tuberculosis of the kidney is of no especial practical interest, but in chronic localized tuberculosis of the kidney it is exceedingly important to make an early diagnosis, as some of the most brilliant successes of modern medicine have been achieved in this field. In the local form there must be caseous degeneration with marked accumulation of tuberculous products. These masses sometimes contain much calcium and appear on the plate as radiopaque smudges, when they are suggestive of kidney stones; but they are differentiated by the irregularity of their outline and by their general appearance, which is alone often sufficient to distinguish them from calculi.

Diseases of the Pelvis of the Kidney.—Diseases of the pelvis of the kidney include: (1) pyelitis; (2) pyelonephritis; (3) hydronephrosis; and (4) nephrolithiasis. Pyelography is a useful expedient in the diagnosis of these conditions.

Renal Outlines.—It is important first to be able definitely to state that both kidneys are present. This is essential for the surgeon who may deem it necessary to remove one organ because of disease, in which case the presence and condition of the opposite one is of exceeding importance. When there is a congenital absence of the kidney on one side the companion usually manifests an enlargement due to compensatory hypertrophy.

There is considerable variation in the size of the kidney in adults so that the exact measure of a normal organ cannot definitely be given. It is obvious, then, that much difficulty presents in endeavoring to decide whether an apparently large renal shadow is due to a congenital large type of kidney or to the beginning hypertrophy of disease. The inexperienced roentgenologist must remember the distortion in the size of x-ray shadows as the result of ray divergence, which varies with the distance between the tube and the plate. In estimating whether a given renal shadow is enlarged a generous margin must be allowed, and it is even

good practice to utilize accessory x-ray diagnostic means, particularly pyelography. Usually an increase in size manifests as an increase in the breadth rather than the length of the kidney, the kidney becoming more rounded. Care should be exercised not to use the distance between the lower rib and the inferior pole of the kidney as a measure of ptosis and enlargement; for normally, in women and in children particularly, the position of the kidney is generally low. In children the size of the kidney is quite deceptive, they being relatively larger than in adults.

The shape of the kidney is usually ovoid, but it may be pointed or even lobulated. Smoothness and symmetry of outline are especially sought in these organs. Occasionally a congenital lobulation without any disease may be observed; but it is differentiated from misshapes assumed as the result of disease by the fact that in congenital deformities other anomalies will usually be elicited in other parts of the urinogenital tract.

The position of the kidney is variable. In estimating it, the migration incident to respiration should be considered. Generally speaking, the x-ray topography of the kidneys is as follows: upper pole between the eleventh and twelfth dorsal vertebrae, lower pole at the lower part of the second and third lumbar vertebrae; so that one can say that a kidney is abnormal in position if its upper pole is on a level with the tenth dorsal or its lower border below the third vertebra. In the female the kidney is reckoned to be half a vertebra lower than in the male, and it is seldom that both kidneys are on the same level, the right as a rule being slightly lower than the left, but this may sometimes be reversed. Another variable quantity is the long axis.

Migration due to respiratory excursion may vary from $\frac{1}{2}$ to 2 inches. In singers the kidney excursion may greatly exceed two inches. The path of the kidney is not alone up and down, but is complicated by a torque resulting from a certain amount of rotation around the pelvis.

Variations in Size.—Abnormally large renal shadows may be due to hypertrophy. One kidney may show a compensatory hypertrophy accompanying either a congenital or acquired disease of the companion.

An enlarged kidney shadow may be due to any of the nephroses, such as hydronephrosis. When due to hydronephrosis the kidney enlargement may affect the organ as a whole or it may manifest localized to one part of the kidney, in which case a distinct bulge of that part of the kidney may be observed. The general appearance of a hydronephrotic kidney is not always to be distinguished on the x-ray plate from the appearance incident to a new growth. If the hydronephrosis is extreme the enlarged kidney may present lobulation. Hydronephrosis affecting the entire organ also involves the pelvis. It is usually impossible to pass a leaded catheter into the kidney in cases of hydronephrosis; by which the x-ray may sometimes differentiate between kidney abscesses, in which latter condition the catheter readily passes into the kidney cavity which has been gouged out by the inflammation.

A new growth shows simply as a diffuse or localized renal enlargement. Tumors of the kidney include: (1) hypernephroma; (2) carcinoma; (3)

sarcoma; (4) teratoma; (5) malignant papillary systadenoma; and (6) certain benign tumors of the kidney (adenoma, lipoma, fibroma, angioma, myxoma). A hydronephroma generally originates at the upper extremity of the kidney just beneath the capsule. It may vary in size from a small sphere the size of a marble to nearly any dimension up to an orange or even larger. It is distinguished on the x-ray plate from nephrolithiasis and other conditions with which it may be confused.

There is nothing to distinguish cystic enlargement of the kidney from enlargement due to other causes.

It is said that renal syphilis produces definite enlargement and marked radiopacity owing to fibrosis. In one case the radiopacity of the kidney was seen to disappear *pari passu* with intensive syphilitic treatment. Atrophy of the kidney is not always easy to discern. When present it may be congenital or acquired. Atrophic nephropathy accompanies tuberculosis so that a small kidney in which radiopaque smudges are present would strongly suggest tubercle infection of the organ.

Perinephritic Abscess.—Doctor Pancoast, in the *American Journal of the Medical Sciences* for January, 1920 (Fussell and Pancoast: "A Roentgen-Ray Sign of Perinephritic Abscess") interestingly discusses a roentgen-ray sign of perinephritic abscess. The report is brief and valuable and bears reproducing in full.

During the study of Case II in this report a curious fluoroscopic finding was observed which directly led to a diagnosis of perinephritic abscess, and which was confirmed by operation. The same fluoroscopic sign was noted in Case I, but in this particular case the diagnosis was certain before the fluoroscopic finding was seen, hence no particular attention was paid to it except to note its presence. So far as either of us can discover this roentgen-ray finding has not been previously reported, though, of course, in the mass of literature a notice of it may easily have been overlooked.

CASE I.—F. H. W., male, aged thirty, was admitted to the University Hospital, under the care of Dr. J. B. Carnett, October 2, 1916, with a diagnosis of renal calculus on the left side. The diagnosis was confirmed by roentgen rays and the stones removed by Dr. Carnett. The patient did well until October 10, when he developed fever of a mild type. On October 25 the fever became septic in type and continued until December 13, when a fluoroscopic examination showed fluid at the seat of the operation. This fluid was demonstrated while the patient was standing in the fluoroscope. The shoulders of the patient were grasped and the patient's body moved quickly two or three times from side to side. Watching the fluoroscopic picture showed a distinct wave in the supposed fluid. This observation was made by Dr. Pancoast. He offered the explanation that a collection of fluid was around the kidney, which showed the wave when agitated. The renal region was opened and a huge sac of pus demonstrated within the capsule of the kidney.

No other opportunity was given to discover whether this sign was an accidental one or whether it was common in subdiaphragmatic collections about the kidney on the left side until Case II was seen.

CASE II.—A. F., male, aged forty-six years, was seen with Dr. Shelly of Ambler, Pa., May 14, 1918. The patient had been sick three weeks, was tired and chilly, and had fever of a septic type. He had pain referred to the base of the left lung. A paracentesis had been performed by Dr. Shelly, who had removed 3 or 4 c.c. of clear fluid with a needle from the base of the left chest. When seen by the writer there was pain and tenderness over the region of the left kidney, but nothing else could be detected. A needle was inserted in the left chest, but the tap was dry.

In the history which was obtained there were symptoms indicative of what was thought to be a peptic ulcer; a tentative diagnosis was made of subdiaphragmatic abscess from a perforating ulcer. He was sent to the University Hospital for a roentgen examination, but this was negative, and he returned the same day.

In a week after this his symptoms still continued; he was again sent to the hospital for careful observation. The symptoms were an irregular fever of septic type, with persistent but slight pain over the region of the left kidney. A roentgen-ray examination, with the patient lying on his back, showed the diaphragm to have the normal arch, and nothing particular could be seen. A plate taken, however, showed a beautiful picture of gallstones, but did not reveal the presence of liquid. Remembering the experience with Case I, the patient was placed upright in the fluoroscope and the first observation was that the left leaf of the diaphragm was flat and was immobile, and had lost its normal arched position.

The patient's shoulders and body were then moved quickly from side to side, and there was distinctly seen the same wave above the renal region which was observed in Case I. This observation was confirmed by both authors and by several other observers.

In view of these facts an exploration was advised in the left lumbar region, with the belief that all of the symptoms were due to a collection of pus in or around the left kidney.

Dr. A. C. Wood, who performed the operation, hesitated to explore the region because the local physical signs of a collection in that region were so slight, but urged that the gallstones be removed and the lesser peritoneal cavity be explored. This, of course, was a rational opinion, but because of the curious fluoroscopic sign he was persuaded to open the kidney region. The incision showed the left kidney tightly bound down by its lower half. But surrounding the upper pole an abscess containing approximately 200 to 300 c.c. of pus was found.

The patient made an uninterrupted recovery and was discharged June 25.

On October 30 the patient developed marked symptoms of gallbladder disease. He was again roentgenographed and the first plates showing gallstones were confirmed. The gallbladder was removed and showed thirteen stones. There was no evidence of previous or present collection of pus in the lesser peritoneal cavity. To-day the patient is well.

This fluoroscopic sign is reported, because we believe it will be of value in certain obscure cases of fever, with suspicious signs about the left kidney, but which signs are not certain enough to warrant an exploration.

In Case I it will be noted the pus was within the capsule of the kidney; no note was made as to the shape of the diaphragm. In Case II the diaphragm had an entirely normal appearance when the patient was lying down and became flattened when the patient was upright. This phenomenon is not clear to us. We have thought of many explanations, but none seem satisfactory. It will be noted also that the amount of fluid was not large, which makes the sign of value in early cases. This second patient was soon relieved, having been in the hospital only about four weeks after operation.

Of necessity, pus about the right kidney will not be expected to give this sign, as the liver intervenes between the kidney and the diaphragm. So far as we know, no such observations of collections of pus between the liver and the diaphragm have been made.

It is confidently hoped that other observers will search for the presence of a wave under the diaphragm in cases of subdiaphragmatic or perinephric abscess when the body is quickly moved from side to side.

(To be continued.)

Staphylococcus - Erysipelas.—Kulenkampff described a characteristic disease picture under this name. The color was a peculiar bluish; formations resembling strings of beads could be felt rather than seen and there were pin head efflorescences and pus vesicles. The margin was not of the typical sharp type seen in ordinary erysipelas.—*Wiener klinische Wochenschrift*.

Medicolegal Notes.

Physician May Testify as to Communications by Patient Made When Third Persons Were Present.—The provisions of the Oklahoma statute that a physician or surgeon shall be incompetent to testify concerning any communication made to him by his patient with reference to any physical or supposed physical disease, or any knowledge obtained by a personal examination of such patient, does not apply when the circumstances surrounding the communication, or knowledge obtained by personal examination, were such as to show that what was said or discovered on the occasion was not intended to be confidential, and especially when third persons who were present and heard all that was said between the deceased and the physician, and the knowledge obtained by a personal examination was as patent to the third persons as it was to the physician.—In re Swartz's Will, Oklahoma Supreme Court, 192 Pac. 203.

Misrepresentations as to Health and Consultations in Application for Insurance.—In an action on a life policy the defense was that the insured in his application had represented himself to be in good health, whereas he was at the time suffering from the disease from which he died, and that he had made material misrepresentations as to consultations with physicians. It appeared that prior to his application he had suffered from some malady causing him pain in the back, which was supposed to be rheumatism, and that he had consulted doctors without obtaining relief. After his death an autopsy showed that he had died of tuberculosis of the spine. The physician who conducted the medical examination on the application testified that the usual physical examination was given the applicant, from which it was not apparent that the applicant was suffering with or had any symptoms of the disease tuberculosis of the spine. He also testified that if the applicant had answered the questions put to him in the medical examination truthfully, the information he would have obtained, if there was a presence of tuberculosis of the spine, would have elicited something to make him suspicious of such a condition. He made a confidential report to the company that he was satisfied everything had been fully stated as to the applicant's physical condition in the application, and that he recommended the applicant for insurance without reservation. He testified that he would not have made the recommendation he did make of the applicant had he given him the information that he had consulted a physician some time previously concerning pains in the back which became more intense and severe after performing hard labor, and that he would have used such information as a basis for finding out the ailment for which the applicant had been under treatment. Three other physicians, in answer to hypothetical questions propounded to them by the defendant insurance company, in which the ailment causing the insured's death and its symptoms were described, testified that the applicant would know, or have reason to believe, he was suffering from some disease, even if he did not know what it was, of a serious nature. On appeal from a judgment for the plaintiff, on a second trial of the case, the judgment was reversed and a new trial ordered for the trial court's refusal to direct a verdict for the insurance company on the ground that the policy was avoided by false statements, in view of Utah Comp. Laws 1917, section 1154, sub. 3.—*Chadwick v. Beneficial Life Ins. Co.*, Utah Supreme Court, 191 Pac. 240.

Fund Owned by Hospital Held Not Subject to Income Tax.—A testator bequeathed his residuary estate to the contributors to the Pennsylvania Hospital, subject to payments to certain annuitants all of whom, save one, have died. The trustee holding the fund invested it in a loan to the hospital. In a suit to recover income taxes, alleged to be illegally collected, it was held that, on payment of sufficient interest to cover administration charges and the annuity to the sole surviving annuitant, the income of the fund was not subject to tax under Act October 3, 1913, nor under Act September 8, 1916, both of which by appropriate provisions declare a purpose to exempt from tax the income of any "corporation or association organized and operated exclusively for . . . charitable . . . purposes."—*Ledere v. Stockton*, C. C. A., 236 Fed. 676.

MEDICAL RECORD.

New York, June 4, 1921.

THE SAFEST SUTURE MATERIAL FOR USE AFTER CESAREAN SECTION.

OUT of a total of 1089 cesarean sections recently studied by Holland, in relation to the suture material employed, in 731 catgut was used, in 288 silk, and in 70 silkworm gut. In a few cases combined deep sutures of catgut and silk or silkworm gut were used, but these are not included in the statistics. The frequency with which these suture materials were used in general works out at 67 per cent. catgut, 26 per cent. silk, and 6 per cent. silkworm gut. The incidence of catgut to silk equals 1 in 2.5. In the cases of ruptured scar, catgut was used in fifteen cases, silk in two and in one case there is no record of the suture material employed, but in no case had silkworm gut been used. The frequency with which the suture materials were used in cases of ruptured cicatrices works out at 88 per cent. catgut, 12 per cent. silk and none in silkworm gut, the incidence of catgut to silk being 1 in 7. The number of silkworm gut cases is, of course, too small to draw conclusions from. It is thus apparent that the incidence of catgut to silk in cases of ruptured scar is nearly three times its incidence in cesarean section in general. From this it might be inferred that scars are nearly three times as liable to rupture after the use of catgut as after the use of silk.

But to this conclusion a reasonable objection may be raised; it may be urged that perhaps very few cases of pregnancy followed the use of silk compared to the number that followed catgut. For example, if only ten or twenty cases of advanced pregnancy or labor occurred among the silk cases, silk would come badly out of the ordeal, with two ruptures to its credit. This objection can quite easily be met and overcome. It is necessary to ascertain the proportion of ruptures to advanced pregnancies among the silk cases, and compare it to the proportion of ruptures to advanced pregnancies among the catgut cases. Holland has supplied this necessary information in the form of tables. These show that fifteen ruptures occurred in 301 cases of advanced pregnancy after the use of catgut, a proportion of 1 in 20; and that two ruptures occurred in twenty-one cases after the use of

silk, a proportion of 1 in 46.5, or about 2 per cent. of the silk cases and 5 per cent. of the catgut cases were followed by rupture in subsequent pregnancy. The liability to rupture after catgut is, therefore, nearly two and a half times that of silk. Put in another way, if silk had been used instead of catgut in the 301 catgut cases, and rupture had occurred in the same proportion as for silk, there would have been only six ruptures instead of fifteen, and the total number of ruptures for all cases would have been reduced from seventeen to eight.

The cause of ruptured scar is imperfect healing, resulting in a thin cicatrix in which muscular union has failed, and which consists of little more than peritoneum and decidua with a varying amount of intervening fibrous tissue. Rupture of the thin cicatrix may be favored by various accidental factors, of which the principle is insertion of the placenta over the scar, with partial separation of the placenta and retroplacental hemorrhage. Other accidental factors are over-distention of the uterus, prolonged or obstructed labor, operative interference, such as internal version, the introduction of hydrostatic bags, and the administration of drugs such as pituitrin. In the reported cases rupture occurred almost as often during pregnancy as during labor—in the proportion of three to four—and many cases have occurred as early as the seventh month of gestation. It would also appear that the scar of the transverse fundal incision is especially liable to rupture and Holland found only one case of rupture of the cicatrix of the cervical incision out of a total of 1605 cases of cesarean section.

PROGRESS OF OUR KNOWLEDGE OF BOTULISM.

THE wide publicity given to a number of cases of food poisoning in various sections of the country in recent years has awakened a lively interest in botulism. That this condition is a toxic entity was shown in 1895 when it was definitely distinguished from the activities of the *B. paratyphosus* and *B. enteritidis*. The latter are infections, while botulism is a pure intoxication. Thus far botulism has been associated with preserved foods only, and not only are the number and variety of these conserves increasing steadily, but new areas of the globe are constantly showing infestation, until the menace of a world endemic looms up. It is the domestic rather than the market product which is the main source of danger. The chief industry of a locality is the one which is apt to be contaminated. Thus in Germany, where sausage foods are extensively consumed, we see sausage poisoning; in Russia, smoked fish poisoning; in California, ripe olives, apricots, and in general preserved fruits and vegetables are involved. Not much is found in medical journals of botulism in animals, but the horse is mentioned as an occasional victim and the so-called "limber neck" of birds is attributed by some investigators to the same bacillus. The hog also is known to suffer

from the disease. In some cases of animal infection spoiled canned food which has been thrown out is evidently at fault.

Marie gives in *La Presse Médicale* for April 23, 1921, xxix, 33, a summary of our present knowledge of the subject, including the latest contributions. He shows that, despite all that has been published to warn the public against the consumption of obviously tainted preserved foods there is nothing to prevent an unscrupulous person from freshening up these substances by washing, spicing, and all the usual means for disguising suspicious tastes, smells, and naked eye appearances. The public has been sufficiently warned against tasting suspected food to see if it is palatable. In the case of a ham or other large article part may be uncontaminated and the rest poisonous. The author, who is a neurologist, regards botulism as easy of recognition when the picture is fully developed. The period of incubation may be from less than one day to a week, but as a rule the symptoms appear in from 18 to 24 hours. Digestion of the poisoned food is normal. The period of gastrointestinal disturbance may in exceptional cases be absent. In addition to some local gastric symptoms like nausea and vomiting there is obstinate constipation—due to the paralytic action of the toxin—with or without meteorism. There is an intense feeling of malaise and depression. The author describes at length the ocular paralyses and mentions that recently lesions of the fundus have been noted. The association of dry mouth and throat with paralysis of the velum causes an intense dysphagia. Ingesta escape through the nose and the voice is nasal. The larynx is eventually paralyzed and the patient speechless. The locomotor system in general is badly compromised and feebleness is associated with ataxia. The cutaneous secretion is much diminished and in general the secretions tend to become abolished although the urine is much less affected in this respect than the perspiration, tears, milk, saliva, etc. Whatever the clinical picture one will find the pulse slow, fever absent, the mind clear and the skin free from exanthems. Spasmodic symptoms are never seen. Death occurs in from four to eight days and the mortality varies from 30 to 60 per cent. according to the epidemic. When recovery occurs it is slow and painful. At autopsy little is apparent to the naked eye but congestions and minute hemorrhages.

In the early stages botulism must be distinguished from other food poisonings. Infection with *B. paratyphosus* or *B. enteritidis* is chiefly apt to follow eating a different class of foods which have not been preserved as eggs, creamcakes, etc., or chopped butcher's meat. Mushroom poisoning is quite distinct and so are ptomaine poisoning and poisoning from fish roe and shellfish. The fact that there are usually several victims makes it an easy matter to locate the source and *a fortiori* the kind of poison.

Of nontoxic conditions intestinal obstruction might require to be excluded while confusion with maladies of the central nervous system and peri-

pheral nerves, including acute poliomyelitis and especially epidemic encephalitis, asthenic bulbar paralysis, polyneuritis, and even hysteria, has occurred. The throat symptoms have suggested post-diphtheritic paralysis and poisoning by the *Solanaceæ* alkaloids. The ocular disturbances have led to confusion with wood alcohol poisoning.

The author goes extensively into the bacteriology of the disease. The bacillus fortunately has not a wide distribution in nature. Attempts to find it in stable manure, soil, etc., have been largely without positive results. Independently of actual disease it has been found a few times in spoiled fruit, mouldy hay, in legumes pierced by insects, in the bodies of insects and spiders, in the excrement of hogs. It is generally known that the *Bacillus botulinus* is avirulent and may be inoculated into animals without injury to them. It simply refuses to multiply in animal tissues. It breeds in dead animal and vegetable tissues like any anaerobe. A point which the author neglects to mention is the presence or absence of an anaerobic symbiosis. It is not apparent whether the bacillus itself decomposes the food-substances or only takes advantage of the action of the ordinary bacteria of putrefaction or at times of fermentation. It is said that the presence of the odor of butyric acid in food suggests the activity of the *B. botulinus*. The same odor is present in pure cultures of the organism. As a rule in descriptions of the food which harbors the bacillus there is no mention of ordinary putrefaction.

PRURITUS ANI AND ITS TREATMENT.

PRURITUS ANI is an exceedingly troublesome affection, the cause of which is not definitely known, and its treatment is not only not curative in the majority of cases but in many instances scarcely alleviative. Its distinctive feature is itching frequently of a most intense character. It is a complaint which seems to be on the increase and is of so great importance that a meeting of the subsection of Proctology of the Section of Surgery of the Royal Society of Medicine in London on April 13 was devoted to a discussion of the subject.

Mr. J. P. Lockhart-Mummery, who opened the discussion, said it was by no means the trivial complaint that its name would imply. The thickening of the skin, the rugæ and eczema, fissures, and other abnormal conditions of the skin around the anal orifice frequently associated with pruritus ani were secondary results of scratching, and beyond the fact that they tended to accentuate the itching and interfere with treatment had no causal relationship to it. He pointed out that certain definite types of pruritus ani were to be distinguished: (1) Those due to some general condition such as glycosuria, etc.; (2) those due to some parasite such as worms, pediculi, etc.; (3) pruritus obviously secondary to some lesion of the anal region, such as fissure, prolapsed pile, etc.; (4) pruritus of old standing where no local lesion can be discovered; (5) paroxysmal pruritus. A local cause for the

itching was present in a great majority of cases, and the first essential was to make a thorough search for this cause. Where a definite cause for the pruritus was discovered it was generally one which produced moisture of the parts, more particularly of a septic character, such as fissure or fistula, a polypus of the rectum, or a prolapsed pile. In the case of itching of recent origin removal of the cause was followed by prompt and permanent relief. The difficult cases were those in which no local cause could be discovered, and more particularly the paroxysmal cases, in which it was unusual to find any local lesion. The speaker confessed himself an adherent of the theory advanced in 1912 by Dr. Dwight Murray that severe pruritus ani of old standing was due to a chronic streptococcal infection of the skin of the anal region, and pointed out that careful investigation by bacteriological methods had proved the presence of *Str. fecalis* infection in the vast majority of cases.

He did not place much reliance on general treatment, but thought local cleanliness and dryness were very important. Lotions and powders were better than ointments. Any local cause, such as fissure, ulcer, piles, hypertrophied papilla, etc., should be removed, and it was often advisable to investigate the anal region under an anesthetic. Dr. Dwight Murray had suggested the use of a vaccine, but it did not seem reasonable to him to treat a septic infection of the skin by vaccine. X-rays applied to the skin through suitable screens had cured about 20 per cent. of his bad cases. Operative treatment remained for the cases in which other measures had failed. The diseased nerve end-plates must be destroyed in order to effect a cure in old-standing cases. In 1905 Sir Charles Ball of Dublin described an operation of division of cutaneous nerves passing to the skin of the anal region and this had proved most satisfactory. During a period of fifteen years he had performed this operation a number of times with excellent results. The patient experienced a return to normal sensation within a month to six weeks, and the relief of the itching was permanent.

In the discussion following the reading of this paper, all were agreed on the absolute necessity of keeping the parts scrupulously clean and dry and not using ointment. It seems that constipation must play a prominent role in the production of pruritus ani because it encourages streptococcal infection. However, it appears more than likely that, generally speaking, the affection is only a symptom brought about or aggravated by unsuitable food, and abstinence from such food will alleviate the condition. Still there is yet much to learn concerning pruritus ani.

KALA-AZAR IN MADRID.

OF recent years not a few exotic maladies have been recognized in Spain for the first time. Some of these have been mentioned at the time in the MEDICAL RECORD. Naturally they are recognized

as a rule on the litoral, or in such other localities as favor intercourse with alien visitors. Kala-azar has been seen repeatedly on the litoral of Spain, but in 1914 a case was found in the city of Madrid in a child which had never left the city, and since then two similar cases have appeared. In the first victim, who was 14 months of age, no exposure could be traced which could in the least suggest contagion or insect propagation. This was also true of the next reported case. The third chronologically was reported originally in the *Archivos Españoles de Pediatría* for December, 1920, an abstract of the article being found in the *Revista Española de Medicina y Cirugía* for March, 1921, iv, 33. The patient was a little girl, 13 months of age, who had been under treatment for supposed angina which did not yield to time or treatment. Eventually the picture suggesting leishmaniasis evolved, although examination of the splenic pulp gave a negative result. Fever and enlarged spleen persisted, although the temperature fell under the use of urotropin given for symptoms of pyelitis. After eight months' delay the parasite was finally found in abundance in the spleen. Antimony injections were pushed until the splenic pulp became negative. The reporters, del Diestro and Barrio, believe that other Madrid cases may have been overlooked. The good results of the antimony treatment were not seen in other Spanish cases. The preparation employed, by intramuscular injection, was an organic combination, the acetyl-para-amino-phenyl-stibiato of sodium. Before resort to this the ordinary tartar emetic had been injected intravenously, but had been renounced because of technical difficulties and parental objections.

IS THERE A PLURALITY OF RABIES VIRUS?

THE possibility of more than one virus has been discussed in connection with many contagious diseases and to-day we speak not of the microorganism of pneumonia, paratyphoid fever, etc., but of groups of such organisms. Puntoni of the Antirabic Institute of Rome discusses the question of a plurality of rabies germs in the *Annali d'Igiene* for January, 1921, xxxi, 1. The author does not refer to differences caused by passage through or adaptation to different animals. He notes that we have two clinical forms of rabies, the paralytic and the violent, but dualism based on this difference does not work out in practice. All the evidence to date has been in favor of unicism. The possibility of a double or multiple virus was suggested by an accident. Since different viruses are numbered there was on hand a virus numbered 223, which had been obtained from a certain dog dead of rabies and which presented the Negri corpuscles. A rabbit inoculated according to custom with this virus died of typical paralytic rabies, after having been, as it was thought, duly immunized. This unique result naturally led to the repetition of the experiment with the brain of the dead rabbit. Two more of the animals were inoculated and were then immunized, one in the usual manner and the other with a vaccine prepared from virus 223. The second animal was successfully immunized while the first succumbed to paralytic rabies. It seemed evident, therefore, that virus 223 was biologically different

from any virus previously known to the laboratory. Further research along the same lines also made for dualism, but the author does not look on the problem as yet settled.

CURE OF GONORRHEA IN A WOMAN BY INTERCURRENT FEVER.

DOHLER reports this case in the *Wiener klinische Wochenschrift* for March 17, 1921, xxxiv, 11. The patient was 36 years old, married for two years, virgin up to the time of marriage, never pregnant, although she had had normal relations, menstruation normal; leucorrhea began soon after the nuptial night and had been treated for months without relief. Examination showed normal internal genitals save for cervicitis, gonococci in the urethra and uterus. It was at this juncture that she developed a fever, apparently from food poisoning, in which the temperature went to 104°. The general condition became much depressed. The patient had been getting protargol bougies in the vagina and urethra and the author comforted her by the statement that the fever would antagonize the gonorrhea. She was not seen from June 26 to September 7 and on the latter date was found free from gonococci. The case was followed up to the end of the year and provocative measures tested to bring back any latent discharge but the disease seemed completely cured. Owing to the severe illness of the woman the treatment of the gonorrhea had been perfunctory; the protargol bougies would hardly have been expected to cure so inveterate a case and credit for the latter must be awarded to the high temperature. From May to December she had lived apart from her husband and thus had not been exposed to reinfection.

News of the Week.

Public Health Committee of the New York Academy of Medicine.—At the meeting of this committee on Monday, May 23, Dr. Cofer, who is in charge of the Quarantine Service, appeared and explained the financial needs of the Quarantine Station. It appears that for a long time little has been done to keep up the needs of the service on Hoffman Island. The water has to be brought to the island by two special boats, there is no satisfactory sewage plant, the barracks need to be enlarged to accommodate 3,500 or more and other changes need to be made. At the lowest estimate the plans call for \$640,000, and the committee is appealing to the United States Senators to secure that amount, the House of Representatives having voted only \$500.

The subject of drug addiction was brought before the committee. It appears that there is a plan to reenact practically the now dead Whitney law into the sanitary code, thus putting New York City under the same conditions that prevailed before this law was abolished. A committee working with the chairman of the Legislative Committee of the County Medical Society, has drawn up some provisions which would possibly make it less difficult for physicians and more practical in its workings. The Public Health Committee approved the plans suggested, but questioned the wisdom of putting the administrative control of drug addiction under the sanitary code.

The committee approved of the plan that the Board of Estimate and Apportionment of this city should purchase the Mohansic property which now belongs to the State and which, by recent legislation, the State has been authorized to sell. This property is part of the land that drains into the New York City water supply and was originally acquired by the State to protest the watershed.

Funds for a Medical University in Jerusalem.—American Jewish physicians gave a dinner at the Waldorf-Astoria on the evening of May 18, at which Professor Albert Einstein and Dr. Chaim Weizmann, president of the World Zionist Organization, were guests of honor. Dr. Nathan Ratnoff, chairman of the physicians' committee, presided, and addresses were made by Dr. A. M. Hilkowich, Dr. Samuel Kopetzky, Dr. Schmaryah Levin, and others. Some eight hundred physicians were in attendance, and it was announced that they had subscribed \$250,000 toward the fund of \$1,000,000 needed to establish a medical university in Jerusalem.

Dr. Walter W. Palmer has been appointed Professor of Medicine at Columbia University and Director of the Medical Service at the Presbyterian Hospital.

Dr. Allen O. Whipple has been appointed Professor of Surgery and Director of the Surgical Service of the Combined College of Physicians and Surgeons of Columbia University and the Presbyterian Hospital.

Dr. Herbert B. Wilcox has been appointed Carpenter Professor of Diseases of Children in the College of Physicians and Surgeons, Columbia University, to succeed Dr. L. Emmett Holt, who resigned after twenty years' service.

Dr. John J. O'Connor, for the past three years resident physician at Gouverneur Hospital, was the guest at a farewell dinner given at the hospital on May 21.

Dr. Walter A. Dannreuther has been promoted from assistant professor to associate professor of gynecology at the New York Post Graduate Medical School and Hospital.

Appropriation to Fight Imported Diseases.—The New York City Department of Health has asked for a special appropriation of \$50,000 to enable it to examine immigrants and to carry on the work of rat extermination along the water front. The committee considering the matter has reported favorably to the Board of Estimate.

Plague in Tampico.—According to a dispatch from Havana, under date of May 26, thirty-eight cases of bubonic plague, with twenty-five deaths, were registered in Tampico, Mexico, and its environs in April and May.

Smallpox in Switzerland.—A near epidemic of smallpox prevails in the German end of Switzerland, the disease having been introduced by travelers crossing the border. Upwards of a hundred cases occurred in Zurich during May, only two of them having been in vaccinated persons. Compulsory vaccination of the entire population is urged in the daily press and by the medical profession.

County Medical Society Makes Recommendations Relating to Control of Narcotic Drug Addiction.—At the stated meeting of the Medical Society of the County of New York, held May 23, resolutions were introduced, affirming that by the repeal of the

Whitney Act, and the failure of Governor Miller to sign the Fearon-Smith bills (which measures had been approved by the New York County Society, but disapproved by many county societies of the State and by the State Society itself), the State of New York is now without adequate provisions of law for the commitment of drug addicts to proper custody for treatment, or for the prosecution of illicit dealers in narcotic drugs; and urging the enactment of an amendment to the Sanitary Code definitely prohibiting any practice of the ambulatory treatment of drug addiction and declaring the possession of narcotic drugs with intent to use or to sell the same for the purposes of addiction to be unlawful. The resolution also protested against any attempt to give force of law, through provisions of the Sanitary Code or otherwise, to those provisions contained in the former Whitney Act or in the regulations issued under its authority, relating to the registration of physicians and the issuance of special licenses to prescribe narcotic drugs; to the registration of addicts and the issuing of special permits for their treatment by a physician who continues to supply them with narcotic drugs for self-administration, and to the compulsory use of official narcotic prescription blanks in triplicate. On the recommendation of the Comitia Minora these resolutions were adopted.

Medical Society Elections.—THE WESTERN ELECTROTHERAPEUTIC ASSOCIATION, at its third annual meeting held in Kansas City, Mo., April 21-23, 1921, elected the following officers for the ensuing year: *President*, Curran Pope, M. D., Louisville, Ky.; *First Vice-President*, L. A. Marty, M. D., Kansas City, Mo.; *Second Vice-President*, G. M. Liston, M. D., Baldwin, Kansas; *Secretary*, Charles Wood Fasset, M. D., Kansas City, Mo., *Treasurer*, W. P. Grimes, M. D., Kansas City, Mo.; *Registrar*, W. F. Roney, M. D., Marysville, Kansas; *Board of Trustees*: C. J. Cunningham, M. D., Kansas City, Mo., and B. B. Grover, M. D., Colorado Springs. The next meeting will be held in Kansas City, April, 1922.

THE WISE COUNTY (VA.) MEDICAL SOCIETY, at its regular meeting held May 2, 1921, elected the following officers: *President*, Dr. J. A. McGuire; *Secretary and Treasurer*, Dr. C. B. Bowyer.

THE HENRY COUNTY (ILL.) MEDICAL SOCIETY, at its spring meeting held in Kewanee, May 5, 1921, elected the following officers for the ensuing year: *President*, Dr. H. L. Fisher, Kewanee; *Vice-President*, Dr. P. F. Roberts, Kewanee; *Secretary-Treasurer*, Dr. C. P. White, Kewanee.

THE MIDDLESEX (MASS.) NORTH DISTRICT MEDICAL SOCIETY at its annual meeting held in Lowell, April 27, 1921, elected the following officers for the ensuing year: *President*, Dr. Andrew J. Halpin; *Vice-President*, Dr. Thomas F. Carroll; *Secretary*, Dr. James Y. Rodger; *Treasurer*, Dr. Thomas B. Smith.

THE LITCHFIELD COUNTY (CONN.) MEDICAL SOCIETY, at its 157th annual meeting held at Canaan, April 30, 1921, elected the following officers for the ensuing year: *President*, Dr. John G. Adair, Canaan; *Vice-President*, Dr. C. N. Warner, Litchfield; *Secretary and Treasurer*, Dr. H. B. Hanchett, Torrington.

THE ARKANSAS STATE MEDICAL SOCIETY, at its

annual meeting, held in Hot Springs, May 2-5, 1921, elected the following officers for the ensuing year: *President*, Dr. C. H. Cargile, Bentonville; *First Vice-President*, Dr. Don Smith, Mount Hope; *Second Vice-President*, Dr. A. W. Elton, Newport; *Third Vice-President*, Dr. J. O. Rush, Forrest City; *Secretary*, Dr. W. R. Bathurst, Little Rock; *Treasurer*, Dr. Saxton, Little Rock.

THE SALINA COUNTY (ILL.) MEDICAL SOCIETY, at its meeting held in Harrisburg, April 25, 1921, elected the following officers for the ensuing year: *President*, Dr. A. J. Butner; *Vice-President*, Dr. L. N. Parish; *Secretary*, Dr. R. B. Nyberg.

THE NORTH CAROLINA STATE MEDICAL SOCIETY, at its annual meeting, held in Pinehurst, April 27-28, 1921, elected the following officers for the ensuing year: *President*, Dr. Hubert A. Royster, Raleigh; *First Vice-President*, Dr. W. T. Parrott, Kingston; *Secretary-Treasurer*, Dr. L. B. McBrayer, Asheville.

THE MARYLAND MEDICAL AND CHIRURGICAL FACULTY, at its twenty-third annual meeting held in Osler Hall, April 23, 1921, elected the following officers: *President*, Dr. A. H. Hawkins, Cumberland; *Vice-Presidents*, Dr. R. W. White, Ellicott City; Dr. Harry Friedenwald, Baltimore; Dr. J. S. Bowen, Mt. Washington, Baltimore; *Secretary*, Dr. J. A. Chatard, Baltimore; *Treasurer*, Dr. C. E. Brack, Baltimore; *Members of State Board of Medical Examiners*: Dr. H. T. Collenberg, Baltimore, and Dr. E. E. Wolf, Cambridge.

THE NORTH CAROLINA STATE HEALTH OFFICERS, at their annual meeting held in Pinehurst, April 26, 1921, elected the following officers for the ensuing year: *President*, Dr. L. J. Smith, Wilson; *Vice-President*, Dr. A. C. Bulla, Winston-Salem; *Secretary*, Dr. F. M. Register, Raleigh.

THE SOUTHEAST MISSOURI MEDICAL ASSOCIATION, at its meeting held in Poplar Bluff, May 6, 1921, elected the following officers for the ensuing year: *President*, Dr. T. F. Frazer, Commerce; *Vice-President*, Dr. Ross, Sikeston; *Secretary*, Dr. Love, Charleston; *Treasurer*, Dr. Gondykootz, Caladonia.

THE STATE MEDICAL ASSOCIATION OF TEXAS, at its meeting held in Dallas, May 10-12, 1921, elected the following officers for the ensuing year: *President*, Dr. Joseph Becton, Greenville; *Vice-Presidents*, Dr. C. E. Durham, Hico; Dr. William Meyers, Sequin, and Dr. S. J. Wilson, Fort Worth; *Secretary*, H. Taylor, Fort Worth.

THE NEBRASKA STATE MEDICAL ASSOCIATION, at its annual meeting, held in Lincoln, May 12, 1921, elected the following officers for the ensuing year: *President*, Dr. B. B. David, Omaha; *First Vice-President*, Dr. Porter F. Dodson, Wilber; *Second Vice-President*, Dr. P. R. Howard, North Bend; *Secretary-Treasurer (short term)*, Dr. E. R. Manning, Omaha; *Secretary-Treasurer (long term)*, Dr. R. B. Adams, Lincoln.

THE CENTRAL ILLINOIS MEDICAL ASSOCIATION, at its 45th annual meeting held in Pana, May 2, 1921, elected the following officers for the ensuing year: *President*, Dr. George Rivard, Assumption; *Vice-President*, Dr. D. M. Littlejohn, Bana; *Secretary-Treasurer*, Dr. F. A. Martin, Pana.

THE SOUTHWESTERN KENTUCKY MEDICAL SO-

CIETY, at its annual meeting held in Paducah, May 10, 1921, elected the following officers for the ensuing year: *President*, Dr. E. W. Jackson, Paducah; *Vice-President*, Dr. W. R. Moss, Clinton; *Secretary*, Dr. Vernon Blythm, Paducah; *Treasurer*, Dr. Frank Boyd, Paducah.

THE ASSOCIATED PHYSICIANS OF MONTCLAIR AND VICINITY, at its meeting held May 17, 1921, elected the following officers for the ensuing year: *President*, Dr. Martin J. Synnott, Montclair; *Vice-President*, Dr. D. Clark Thompson, Bloomfield; *Secretary*, Dr. Allan S. Kirkwood, Montclair; *Treasurer*, Dr. John H. Young, Montclair; *Historian*, Dr. Henry Wallace, Glen Ridge.

THE LOGAN COUNTY (ILL.) MEDICAL ASSOCIATION, at its annual meeting held in Lincoln, May 12, 1921, elected the following officers for the ensuing year: *President*, Dr. C. B. Caldwell; *First Vice-President*, Dr. Forrest Van Hook, Mt. Pulaski; *Second Vice-President*, Dr. J. H. Butler, Lincoln; *Secretary-Treasurer*, Dr. E. C. Gaffney.

THE ORANGE COUNTY (CAL.) MEDICAL SOCIETY, at its annual meeting held in Santa Ana, May 4, 1921, elected the following officers for the ensuing year: *President*, Dr. J. H. Lang, Fullerton; *Vice-President*, Dr. A. H. Domann, Orange; *Secretary*, Dr. W. C. Mayes, Santa Ana; *Treasurer*, Dr. D. C. Cowles, Fullerton.

THE HAMPSHIRE MEDICAL SOCIETY, at its meeting held in Northampton, Mass., May 11, 1921, elected the following officers for the ensuing year: *President*, Dr. A. J. Bonneville, Hatfield; *Vice-President*, Dr. C. E. Perry, Northampton; *Secretary and Treasurer*, Dr. E. E. Thomas.

THE HOMEOPATHIC MEDICAL SOCIETY OF THE STATE OF MICHIGAN, at its meeting held in Grand Rapids, May 12, elected the following officers for the ensuing year: *President*, Dr. F. B. McMullen, Detroit; *First Vice-President*, Dr. C. E. Beeman, Grand Rapids; *Second Vice-President*, Dr. C. B. Stouffer, Ann Arbor; *Secretary-Treasurer*, Dr. Milton A. Darling, Detroit; *Corresponding Secretary*, Dr. Scott Runnels, Ann Arbor.

THE ILLINOIS STATE HOMEOPATHIC MEDICAL SOCIETY, at its 63rd annual meeting held in Chicago, May 12, elected the following officers for the ensuing year: *President*, Dr. G. E. Dienst, Aurora; *Vice-Presidents*, Dr. C. A. Harkness, Chicago, and Dr. Hyde West, Woodstock; *Secretary*, Dr. J. H. Reece, Palatine; *Treasurer*, Dr. Rich H. Street, Chicago.

THE ELGIN (ILL.) PHYSICIANS' CLUB, at its regular meeting held May 11, 1921, elected the following officers for the ensuing year: *President*, Dr. Ralph T. Hintano; *Vice-President*, Dr. H. W. Dueringer; *Secretary and Treasurer*, Dr. Olive H. Kocker.

Obituary Notes.—DR. ENOCH AUSTIN JACKMAN, a graduate of the University of Vermont College of Medicine in 1886, died suddenly at his home in Wadsworth, Nev., on May 5 at the age of sixty-three years. He was for many years physician for the Southern Pacific railroad and at the time of his death was justice of the peace of Wadsworth township.

DR. JOHN S. WOOD of Cleveland, a graduate of the Western Reserve Medical College in 1876, died

suddenly of heart disease on May 6, at the age of sixty-eight years. He was well known as a collector of rare and first editions of books and etchings.

DR. A. M. POTTER, a graduate of the Cincinnati Medical College in 1871, died at his home in Springfield, Ohio, on May 5, at the age of seventy-one years.

DR. RUDOLPH HEYM, a graduate of the Homeopathic Medical College, Cleveland, in 1876, died at his home in Springfield, Ohio, on May 7, at the age of seventy-one years.

DR. WILLIAM G. COCHRANE, formerly of Bloomington, Ill., died in Los Angeles, Cal., on May 4, at the age of seventy-six years. He was graduated from Rush Medical College in 1869.

DR. ALDER E. SMITH of Freeport, Ill., a graduate of the Chicago Homeopathic Medical College in 1884 died on May 3, at the age of sixty-one years. He was a member of the Illinois Homeopathic Medical Society and the Illinois Tuberculosis Society. He served as a surgeon during the Spanish-American War.

DR. ROBERT BOLT DAY of Pendleton, S. C., died in a local sanitarium of a complication of diseases on May 8, at the age of forty-seven years. He was a graduate of Barnes Medical College, St. Louis in 1897, and served in the Medical Corps of the Army during the recent war.

DR. LEO J. HINES of Oaklawn, R. I., a graduate of the College of Physicians and Surgeons, Baltimore, 1905, died at his home on May 2, at the age of forty years.

DR. JOSEPH COMB MARARDA, formerly a resident of Woonsocket, R. I., died of paralysis at his home in Montreal on May 7, at the age of seventy-six years.

DR. GEORGE M. STITES of Williamstown, Pa., a graduate of the College of Physicians and Surgeons, Baltimore, in 1882, died at his home on May 1, at the age of sixty-one years.

DR. WILLIAM ALLEN BROOKS of Brookline, Mass., died of heart disease in his private hospital there on May 20, at the age of fifty-seven years. He was graduated from the Harvard Medical School in 1891.

DR. FRANK AUGUSTUS BRYANT of New York City, a graduate of Bellevue Hospital Medical College in 1895, died at the White Plains Hospital on May 17, at the age of seventy years. He was a member of the American Medical Association and the New York Academy of Medicine.

DR. N. N. JOHN NEILSON of Chicago, a graduate of the University of Illinois College of Medicine in 1903, died suddenly on May 14.

DR. EDWARD O. PORTER of Cornwall, Vt., a graduate of Castleton Medical College, Castleton, Vt., in 1859, died on May 5, at the age of eighty-six years.

DR. ELBERT JUDSON CLARK, a veteran of the Civil and Indian wars, and for many years a practitioner at Winnebago, Ill., died at the home of a relative in Cleveland on May 8, at the age of seventy-four years. He was a graduate of the Northwestern University Medical School in 1871.

DR. J. F. GRABILL of Elyria, Ill., a graduate of the Miami Medical College in 1880, died suddenly on May 12, at the age of sixty-five years.

DR. ROBERT R. JETER of Goshen Hill, S. C., a

graduate of the Medical College of South Carolina in 1889, died on May 7, at the age of fifty-four years.

Dr. D. W. RAMER of Bethlehem Church, Tenn., a graduate of the University of Nashville Medical School in 1874, died on May 12, at the age of seventy-one years.

Dr. WILLIAM H. ROBERTS of Terre Haute, Ind., a graduate of Jefferson Medical College in 1861, died on May 8, at the age of eighty-one years.

Dr. WILLIAM C. POWELL, JR., a graduate of Hahnemann Medical College, Phila., in 1911, died of typhoid fever on May 5, at his home in Bryn Mawr, Pa., at the age of thirty-six years.

Dr. PIERRE N. BERGERON of Philadelphia, Pa., died from blood poisoning, the result of pricking his finger while performing an operation on May 11, at the age of fifty-three years. He was graduated from Jefferson Medical College in 1898.

Dr. ARTHUR SCRIMEGEUR, a graduate of Long Island College Hospital in 1909, died at his home in Bridgeport, Conn., on May 11, at the age of thirty-eight years.

Dr. HARRY HARPER GREEN of Paines Hollow, Va., a graduate of the Geneva Medical College, New York, in 1859, died on May 9, at the age of eighty-three years.

Dr. REMUS G. ELLIOTT of Greenville, S. C., a graduate of the Medical College of the State of South Carolina in 1881, died on May 8, at the age of sixty-two years.

Dr. EDWARD KIRKLAND, a graduate of the Hahnemann Medical College, Phila., in 1886, died at his home in Bellows Falls, Vt., on May 2, at the age of fifty-nine years.

Correspondence.

A MESSAGE OF HOPE. NO 2.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—In your issue of May 21 there is a letter from my friend Dr. Henry C. Coe, criticizing certain few excerpts which the *New York World* saw fit to make from my letter to you published February 12. In this letter, under the title "A Message of Hope," I took exception to the use of that expression regarding the purpose and result of the work of the American Society for the Control of Cancer during the eight years of its existence. I wish that Dr. Coe had consulted my original letter instead of the meager abstract by the editor of the *New York World*, for, if he is interested in the society I should like to have had him answer the questions which I there proposed.

Some of us who for many years have been in constant contact with cancer, largely with the deplorable cases which have been submitted to surgery, x-ray, radium, etc., and who have watched the steady rise in its mortality during the years of the existence of the society, have wondered what the latter had accomplished in the way of controlling the disease, and what its members propose to do in order to effect the result longed for by all.

Dr. Coe criticizes the figures I gave from the United States Mortality Reports, and then quotes the well-known statistician, Mr. Hoffman, as saying that the mortality from cancer "had not risen since

1915, but remained steadily at 80 per 100,000. I do not know where he gets his figures from, but until better official figures are furnished we must rely on those "imperfect statistics" (Dr. Coe) given by the United States officials. I have the large quarto volumes furnished by the Census Bureau now before me, and find that in 1916 the rate was 81.8 per 100,000 population, in 1917, 81.6 per 100,000, while in 1918 it had fallen to 79.8 per 100,000. This late improvement may possibly have been partly owing to the strenuous opposition to surgery on all sides, and probably also in part due to the prevalence of more wise and rational views regarding cancer, and a more humane and successful internal treatment, now so widely accepted.

My statement, however, which statistics prove, was that "in the year 1915, which directly followed the crusade of over-zealous surgeons throughout the country propagating ideas" (regarding the local nature of the disease, and urging immediate and radical surgical removal of every blemish or lesion which one chose to call precancerous) "there was a rise in cancer mortality which was actually more than double the average rise during the preceding five years," as shown by the United States statistics; this cannot be refuted.

Dr. Coe indirectly attacks an incidental remark which I made including the word "radium." What I said in my former letter was that "a recent study of the death statistics of the Board of Health of New York City has revealed the alarming fact that during the period from July 1 to December 31, 1920, the deaths from cancer had actually exceeded those from tuberculosis by 22—2,691 to 2,669, and this in spite of radium aiding surgery." He intimates that I have "not given sufficient attention to this subject to speak *ex cathedra*," though I did not speak *ex cathedra*, but only mentioned a fact which everyone knows. In regard to radium, while I have not had very great personal experience with it, I have paid particular attention to its effects for years, in dozens or scores of patients, private and public, in whom it has been employed; in some of these there have been beneficial results, temporary at least, in others negative, and in still others decidedly harmful results. I have also followed its literature closely and written a long chapter on x-ray and radium in cancer in my new book, and have observed its application for months, at a certain hospital where it is largely and intelligently used. I agree that, with the x-ray, it forms a good adjuvant when needed in certain cases of cancer, if associated with the proper dietetic, hygienic, and medicinal treatment of the disease.

In regard to this latter Dr. Coe states that he has had no experience along this line, but questions my statement that "with minute and proper dietetic hygienic, and medicinal treatment not only early lesions be made to disappear, but metastases yield, and the cancerous habit be overcome, and the patient remain well indefinitely, provided the proper course is pursued indefinitely." This has been so abundantly shown by various cases which I have reported in full in my writings, that no further comment is necessary.

I wish that Dr. Coe, as a member of the American Society for the Control of Cancer, had answered the suggestions which I made in my former letter. The

public would like the society to state what they claim has been accomplished toward the "control of cancer," from which disease all surgeons agree that 90 per cent. of those once afflicted still die, and from which there are still about 80,000 deaths per year in the United States. Also what they are doing to help the 300,000 sufferers from cancer now existing in the United States, with at least 80,000 new cases yearly, to make up for the deaths. Furthermore, what they are doing to prevent the millions of people who fear cancer from acquiring the dire disease.

L. DUNCAN BULKLEY, M.D.

OUR LONDON LETTER.

(From Our Own Correspondent.)

LONDON, May 13, 1921.

Lunacy in London.—Last year's lunacy returns for London show that the total number of patients, parish, criminal and private, on January 1 last, for whom the County Council had to find accommodation was 17,816 (7213 males and 10,603 females), as compared with 17,296 (7019 males and 10,277 females) on Jan. 1, 1920, an increase of 520, the largest recorded since 1905. Although there was some increase in the number of fresh cases of insanity admitted during the year, the total rise is accounted for largely by accumulation caused by low death and discharge rates. The total number of ascertained lunatics belonging to the County of London (including those in the Metropolitan Asylums Board's institutions, in workhouses, or with relatives or friends, as well as those for whom the Council was responsible) was 23,567, as compared with 22,915 on Jan. 1, 1920, an increase of 652.

Large Gift to Found a Hospital.—Sir Ernest Cassel has recently declared his intention of devoting the sum of £225,000 to the object of founding and endowing a hospital or sanatorium for the treatment of functional nervous disorders. Such disorders loosely termed nervous and which are not associated with obvious structural changes are, perhaps, largely the result of the manner of modern life and have increased very considerably during and since the war. Also, these disorders cause a good deal of suffering and sometimes result in mental and physical consequences of the gravest nature. However, as is well known, and as was proved conclusively during the war, these disorders can be treated successfully, given favorable conditions, and it was to provide such means that this institution has been founded. Sir Ernest Cassel has purchased as a home for the institution a magnificent mansion and park in ideal surroundings near London. The house, which has been reconstructed for the purpose, will accommodate about sixty patients, and it is chiefly intended for those members of the educated classes who are unable to afford the expenses of a nursing home.

Athletics for Girls.—In this country girls have been going in for athletic exercises of every kind in the most strenuous manner possible. They not only play lawn tennis vigorously, but many of them play cricket and football. Moreover, in many, perhaps in the majority, of the schools for girls, nearly as much attention is paid to physical

as to mental culture. While it is agreed on all hands that a certain amount of this sort of training is beneficial, it is argued by many who ought to know that the system is being carried to excess, and that if moderation is not exercised in this direction, the results from all points of view will be injurious if not actually disastrous. A campaign has just been inaugurated against the continuance of the present system. At a meeting in London on the evening of May 10 last a resolution was passed by an audience of head mistresses of girls' schools and of ladies who have made a study of physical culture, protesting against the existing methods of physical education for girls as something injurious to future generations, and a small committee was formed to draw up and circulate a manifesto on the subject. In a letter of sympathy with the movement from Sir James Crichton Browne it was pointed out that physical exercise and training are as necessary to girls as to boys, but these must have regard to physiological and developmental considerations. To ignore sexual differences is to court disaster in the long run. Dr. Arabella Kenealy presented the question from another point of view, stating that women who develop masculine instead of female attributes do this at the cost of the male potential, which is transmitted by the father to the daughter in trust for the male line. Athletic women produce female offspring mainly, and seldom have sons. When sons are born to them, these are apt to be puny and delicate, or generally emaculate or of inferior type. The cultured classes, who are chiefly affected by athletic training, are failing to provide sons of the fine physique and many talents and initiative which have set the Anglo-Saxon race in the van of evolution. Miss Cowdroy, the principal of a girls' high school in the vicinity of London, who moved the resolution of protest, said that the girl who had been trained to hockey, cricket, and football suffered at childbirth. Sometimes the child suffered and sometimes the mother; sometimes one of them died. Medical men had told her that difficult confinements could often be traced to strenuous sports. Eighty per cent. of the girls she had known who had been trained to become gymnastic mistresses had been incapacitated for motherhood. A girl had a large store of vital and nervous energy which she could draw upon, if normally developed, at the great crisis of motherhood. That strength was a deposit account; but if she used it as a current account, as a boy could afford to do, her children would pay the bill. She believed that the Victorian girl was a better mother than the modern athletic girl.

Although some of the above statements seem somewhat exaggerated, and while Dr. Kenealy's views are somewhat hypothetical, it doubtless is the fact that physical culture for girls is often considerably overdone. Of course, it must not be forgotten that the personal equation enters into this question largely, and that what is one girl's meat is another girl's poison. However, speaking generally, the cultivation of athleticism has become quite a fetish with the modern British girl whose parents can afford to indulge these tendencies. It is another proof of her emancipa-

tion and of her equality with man. The home-loving woman, endowed with the old-fashioned virtues, is decried, when not derided, and the ambition of the modern girl is, or so it appears, to differ in every respect from the girls of the Victorian era. It is more than possible that the present craze for athletics among women is only a phase, a revolt from former conditions; the pendulum has swung too far. What is really required is the happy medium, if that can be determined. American medical men should be able to speak with a good deal of authority regarding athletics for women, as the craze is probably as manifest in the girls' colleges in your country as in the girls' schools here.

Psychoanalysis.—At a recent talk given at St. Paul's Church, Covent Garden, Dr. W. E. Orchard, a well-known nerve specialist, criticized severely the methods of psychoanalysts of delving into the unexplored depths of the mind. He said that repression plays a part in life, and that what has been repressed should not be disturbed. He pointed out that as he passed along the street he heard a great number of filthy, unclean, and unpleasant words. He never used them himself, but they were all in his mind. If he went out of his mind, the first thing to happen might be a constant flow of filthy language from his lips. He could if he chose sit down and write as fine a collection of filthy expressions as any porter in Billingsgate. They were in the dust bin of his mind, but in his opinion the dust bin should not be disturbed. Moreover, Dr. Orchard held that the psychoanalysts had built up their theories on the study of pathological subjects. They did not study the normal, but the abnormal, and they had not always been careful enough to see that all possibility of suggestion to the patient was cut off. The remedy, he thought, was frequently worse than the disease.

Interesting Figures in Connection with the Tuberculosis Bill.—In moving the second reading of the Tuberculosis Bill, introduced recently into the House of Commons, the Earl of Onslow said that the number of deaths from tuberculosis in this country and the rate per 100,000 of the population for each year since 1915 were as follows:

Year	Deaths	Rate per 100,000
1915	54,295	151.5
1916	53,855	152.9
1917	55,931	162.4
1918	58,073	169.4
1919	46,312	125.8
1920	42,545	112.8

The fall in the rate of 56.6 per 100,000 between 1918 and 1920 was attributable partly to the cessation of the war and consequent better living conditions, and partly to the valuable work done by the councils. The increase of facilities for the treatment since 1912 was as follows:

	Number of Beds in Public Institutions	Dispensaries
1912	1,500	8
1918	6,719	37
1921	9,879	470

At the same time, the beds in voluntary institutions had increased from 2800 in 1912 to 7568 in 1921. This gave a total increase of beds from 4300 in 1912 to 17,447 in 1921. It was the fixed policy of the Government to continue this institutional treatment.

1. Studies on the Bacteriology of the Alimentary Tract.—N. Mutch and Jane Mutch record these observations, made in the wards and bacteriological laboratory of Guy's Hospital, London, which they summarize as follows: (1) Glycophyllia is a property peculiar to streptococci of alimentary origin, and is almost universal among the streptococci present in the bowel. It may therefore serve as a criterion for the differentiation of streptococci of alimentary origin from other streptococci. (2) The proportion of streptococcal strains at any point which possess extreme glycophyllia increases progressively at successive intestinal levels from mouth to anus. (3) A streptococcus can possess extreme glycophyllia and at the same time considerable infective power. Such an organism is particularly well equipped for the evolution of chronic infection of the bowel. (4) A well defined pattern of distribution of *Streptococcus longus* in the alimentary canal has been observed. (5) Extensive streptococcal infection of the small intestine may exist even when repeated cultivation of the feces fail to yield any growth of *Streptococcus longus*. (6) The presence of carbohydrate is the most potent factor in determining the dominance of glycolytic streptococci over *Bacillus coli* at any level of the intestines. Laboratory experiments with symbiotic coefficients and clinical observations are recorded in support of this statement. (7) Absolute suppression of *Bacillus coli* by glycolytic streptococci takes place when the hydron concentration is measured by $\text{Ph}=5.2$. The streptococcus itself dies if the Ph falls below 4.6. (8) *Streptococcus fecalis*, as well as glycolytic *Streptococcus longus*, can suppress *Bacillus coli* when grown in glucose broth. This property is also possessed by a small proportion of long-chained cocci from the mouth. (9) The following factors appear to control the evolution of chronic streptococcal infection of the bowel: (a) the presence in the mouth of centers for the production of glycolytic streptococci, (b) impaired digestion, (c) Loci of stagnation in the intes-

tines. (d) Diminished resistance of the tissues generally or locally.

13. Therapeutic Management of Arteriosclerosis and Its Relation to the Etiology of this Disease.—N. Philip Norman describes a method of treating arteriosclerosis which, he considers, seems to offer a prompt and more permanent relief for this disease than the current methods now in practice. It is based on the theory that arteriosclerosis is the direct result of infection. Every infection, disease, or disorder from which one may suffer, whether or not a microbic cause, can be demonstrated, leaves its imprint, so to speak, its clearities, upon the organisms. If this theory be correct, the first step is to localize and remove the foci of infection, whether these be in the teeth, the tonsils, the sinuses, the gall bladder or the intestinal tract. The technique described deals with colonic infection. It involves the determination of the type of infection to be dealt with and an attempt to determine the deformity of the colon, especially that related to the sigmoid and descending colon, by abdominal palpation and proctoscopic and sigmoidoscopic examination, and later, when irrigating by the sense of touch which one acquires by passing a colonic tube, a soft rubber tube from three-fourths to seven-eighths of an inch in diameter and forty inches in length is used. Two percolating jars are necessary for the irrigating solution and each should hold two gallons. A three-way valve in one position allows of the flow of the fluid from the percolating jars into the colon, and, when reversed, cuts off the jars and allows the fluid to syphon from the colon into the waste jar. The solutions used depend upon the stool examination. For instance, if highly acid, a sodium carbonate solution is used until the stool is rendered neutral or alkaline. From one to three gallons of solution are used every day, until the tube passes through the sigmoid, into the descending, and, if one is fortunate, into the transverse colon. It usually requires from ten to twelve consecutive daily irrigations to cleanse the colon, and when this has been accomplished one is ready to implant the colonic tract with live, uncontaminated cultures of the *Bacillus acidophilus*. This bacterium being lactic acid formers, creates an environment unfavorable for the growth of the pathogenic organisms, and it also stimulates the diseased mucous membrane to heal. The culture is kept up until a good growth is obtained. After this the *Bacillus acidophilus* is implanted about once every ten days until permanency of growth is assured. When the patient's alimentary tract has been thoroughly disinfected, and granting that the possibility of a syphilitic infection has been eliminated, it becomes logical to assume that the patient has been given every chance of staying and improving the arteriosclerotic process. The readjustment of the blood pressure level is accomplished slowly, and this readjustment is in keeping with the metabolic compensation necessary.

1. Acute Rheumatic Fever and Its Variants in Childhood and Adolescence.—David Riesman reminds one that rheumatism is not, like typhoid fever or diphtheria, a unit disease, manifesting itself in a more or less uniform manner; the "rheumatic chain," on the contrary, has a number of apparently dissimilar links, the connection of which with rheumatic fever is not always easily established. There is abundant evidence, however, that such connection exists. Among these links may be mentioned chorea, tonsillitis, rheumatic skin affections, especially rheumatic nodules, cerebral rheumatism, acute rheumatic polyarthritis, and rheumatic carditis. In childhood, the disease presents certain important peculiarities: (1) Though occurring in children of all ages—even intrauterine infection has been described—

it is most frequent between the ages of five and fifteen years, and is especially common about the period of puberty. It seems to affect girls a little more frequently than boys, which is interesting in view of the fact that in the adult the male sex greatly predominates over the female. (2) The joint involvement is often slight; indeed, so slight as to be easily overlooked. The so-called growing pains are frequently rheumatic signals. (3) Involvement of the heart is very common in children. Neither its occurrence nor its intensity bears any definite relation to the severity of the joint involvement. Trivial joint involvement may be followed by severe cardiac damage. (4) Tonsillitis, follicular tonsillitis, is a frequent pre-occurrence in the acute attack, and is a common antecedent in the patient's history. (5) Chorea is a sequel in a number of cases. (6) Skin manifestations are more common in children than in adults. (7) Cerebral rheumatism, characterized by delirium and hyperpyrexia, is rarely seen in childhood, but is a complication of the disease in adults. In making the diagnosis one should always be skeptical when only one joint is involved. In adults, this is practically never acute articular rheumatism. In children it may be; but if the pain persists and is sharply localized in one joint or in its neighborhood, the probabilities are that the condition is an osteomyelitis, a tuberculous process, or, in infants, Barlow's disease or scurvy. The early occurrence of endocarditis or pericarditis is a point in favor of the rheumatic nature of the trouble. The acute stages of polyarthritis, arthritis deformans, or infectious arthritis may resemble acute articular rheumatism. However in the former the small joints are predominantly involved, especially those that are rarely attacked by articular rheumatism, as, for example, the sternoclavicular, the temporomaxillary and the vertebral joints. The inflammation does not shift so rapidly from joint to joint, and heart complications are exceedingly rare. Gonorrheal rheumatism in its acute stages may be mistaken for acute articular rheumatism; but the history, the presence of the gonococcus in the prostatic secretion, the inefficacy of the salicylates, and the complement fixation and precipitin tests assist in the diagnosis. Endocardial involvement is quite common in gonorrheal arthritis; pericardial, while it occurs, is rare. Treatment resolves itself largely into the use of the salicylates, morphine where the pain is excruciating, local measures, water in abundance, and the diet of all febrile diseases. The use of vaccines and serums is purely empiric at present, but this does not of necessity condemn their employment. General prophylactic care in the matter of clothing and the avoidance of exposure to wet and cold, should be observed. Tonsilectomy is justifiable if the tonsils are diseased.

3. Iodine in the Cerebrospinal Fluid, with Special Reference to Iodid Therapy.—Earl D. Osborne presents the tabulated results obtained with normal spinal fluid, after the administration of potassium iodide by mouth, after administration by rectum only, and at varying intervals after an intravenous injection of 10 per cent. solution of sodium iodide. Four case histories are presented in brief. These four observations point to one or both of two possibilities: Either the meninges are more permeable to iodine compounds when there is meningitis, or tissue actively involved by syphilis takes up more iodine than normal tissue. The data presented suggest the possibility that the iodine content of the cerebrospinal fluid following iodide administration may be of diagnostic importance in the study of diseases of the central nervous system. From this study the following conclusions are drawn: (1) Iodine is present in the cerebrospinal fluid of normal individuals. (2) Iodine in increased amounts, is present in the cerebrospinal fluid following the administration of iodides by mouth, by rectum and intravenously. (3) The iodine content of the cerebrospinal fluid following administration of iodide by mouth or rectum is small compared with that following the administration intravenously. (4) The iodine content of the cerebrospinal fluid following the administration of iodide intravenously plots a definite curve, depending on the amount administered. (5) Certain observations made in the course of this study suggest the possibility that (a) neurosyphilitic tissue takes up more iodine than normal nervous tissue, and (b) the presence of a meningitis increases the permeability of the meninges to iodine compounds in the blood.

2. The Production of Bactericidins by Micro-Organisms.—J. W. McLeod and P. Govenlock state that a considerable amount of evidence has been brought forward to show that in the course of reproduction many bacteria produce substances inhibitory to their own growth and to that of other bacteria. In the case of the pneumococcus we believe that we have obtained conclusive evidence that such substances are produced and that they are relatively labile bodies destroyed by heat at 80-85° C. A free supply of oxygen seems to be important for their production, and it seems possible that it is in this fact that we have the explanation of the therapeutic value of oxygen administration in pneumonia. The possible application of these findings are various. They have considerable theoretical interest, in the sense that a class of substances, perhaps of the nature of enzyme, which has not as yet been seriously investigated, is brought under examination. Further, it may be possible in taking those substances into account to elucidate some pathological and bacteriological problems till now obscure, such as the crisis in pneumonia or the predominance of certain types of bacteria in different parts of the alimentary tract. Among the likely practical applications are mentioned a better understanding of the factors dealt with in preserving stock cultures and in obtaining growths of "delicate" bacteria; also the production of media capable of promoting selective bacterial growth, e.g. it may be possible to prepare a medium capable of growing cholera and not *B. coli*, etc. Lastly it is remotely possible that such substances may have a therapeutic application, since it may be that pneumococcal product which kills staphylococci and leaves streptococci much less affected may be more lethal to the former than it is to the issues of the body.

3. Observations on the Mobile Ascending Colon.—E. R. Flint summarizes his views on this subject: The colon has a considerable degree of mobility. There is frequently a band present which prevents undue movement of the cecum across the true pelvis. The statement that a mobile proximal colon exerts a drag on the other viscera requires further evidence before it can be accepted. It is not proved that the mobility of the colon accounts for the formation of ulcers, or even for dyspeptic symptoms; the same symptoms occur when the colon is fixed. Colopexy is indicated for certain cases, and the symptoms in such cases may simulate appendicular colic. Colectomy is indicated when the cecum is obviously acting as a "cesspool" and the results of hemi-colectomy are as good as, and the risks much less than, those of complete colectomy.

1. Workmen's Compensation: The Surgeon's Fee and the Carrying Insurance Company. George Chaffee.
2. True Intestinal Pain (Continued). W. H. Foreman.
3. Calcipriva Stigmata in Heart Disease. John Aulde.

2. True Intestinal Pain.—W. H. Foreman concludes the discussion of this subject by a categorical summary: (1) Functional digestive disturbances rarely occur in the stomach and small bowel adequate for a distress or pain. (2) Nature limits and controls bacterial fermentation in the colon: (a) By relative complete digestion and absorption in the small bowel. (b) By continued digestion and absorption of liquid food residue in the proximal colon. (c) By solid food residue in the remainder of the colon. (3) Cathartics, enemas, rough foods, heavy oils, carbonated drinks, roughage, not only are mechanical and chemical irritants, but they produce changes

within the colon which result in bowel overtone or spasm adequate for distress or pain, and establish an intestinal toxemia by softening or liquefying the colon contents, and interfere with proper elimination. (4) The equilibrium of the viscera is maintained by the two systems of vegetative nerves, the one activating and the other inhibiting action. Symptoms appear when this equilibrium is disturbed. (5) The great mass of visceral stimuli are never adequate to reach consciousness, but are only concerned in unconscious physiologic function. (6) In visceral disease the cerebrospinal nerve centers become hyperirritable from constant amplified stimuli, so that their threshold of response is lowered, and impulses which are normally unnoticed may penetrate the nerve synapses and reach consciousness, likewise exaggerated reflexes may induce bowel tone or spasm adequate for distress or pain. (7) Psychoses and neuroses or organic disease of the nerve centers may result in altered nerve response adequate for pain. (8) The endocrine system is a very important factor in bowel tonus and true intestinal pain. (9) Bowel tone and true intestinal distress or pain are influenced by: (a) Conditions in the bowel itself or in its walls. (b) Reflexes from other structures through the vegetative nerves. (c) Hyperirritability of the cerebrospinal nerve centers due to visceral disease. (d) Psychoses and neuroses or organic disease of the nerve centers. (e) Endocrine secretions.

4. Deep Furrows. Grace M. Cook.

2. Perforated Gastric Ulcer.—M. C. Sexton, in reporting two fatal cases, emphasizes the point that patients on whom operation is performed for perforated ulcer die most frequently from the following causes, in the order named: (1) shock; (2) septic peritonitis, due either to too long delay before operation or to imperfect surgery; (3) pneumonia. Early diagnosis, early surgery, scrupulous postoperative care and rigid attention to detail are the essential factors in the successful management of these cases.

2. The Drug Armamentarium of the Endoscopist. Chevalier Jackson and William H. Spencer.
3. The Diagnosis and Treatment of Conditions of the Heart Complicating Pregnancy. Edward P. Davis.

3. The Diagnosis and Treatment of Conditions of the Heart Complicating Pregnancy.—Edward P. Davis emphasizes the importance of including in the general examination of every pregnant patient, an examination of the heart and the vascular system by taking the blood pressure and observing the presence or absence of dilated veins. If the examination reveals a heart murmur, irregular and rapid heart action, rapid pulse, of variable tension, perhaps slightly raised, yet gives no reason to believe that organic disease has developed, the hygiene of pregnancy should be strictly enforced. Under ordinary circumstances, if the patient has a naturally sound constitution and her hygiene is good, such a condition is in no way serious and will gradually disappear as pregnancy advances. In considering actual lesions of the heart complicating pregnancy attention must first be drawn to those of congenital origin. One thinks at once of patulous foramen ovale, but this is not the important congenital lesion in these cases. The most important congenital lesion in these patients is that affecting the mitral orifice and producing mitral stenosis. A patient with a congenital heart lesion complicating pregnancy should follow a strict hygiene. In acquired diseases of the heart complicating pregnancy, the most important is mitral regurgitation. This often follows rheumatism in childhood or at adolescence, or perhaps repeated attacks of tonsillitis. On examina-

tion the usual signs of regurgitation are present. The presence of the murmur over this area is not of primary importance in diagnosis or prognosis, or in suggested treatment. The question is not the presence or absence of the mitral lesion, but whether compensation is present. Should compensation rapidly fail, despite hygiene and care, the indication at once arises to terminate the pregnancy. This should be done in the manner least calculated to bring strain and suffering upon the patient. If section is to be the mode of delivery, the question of sterilization must be considered. In cases of aortic and mitral stenotic disease, the question of sterilization is sometimes difficult to solve. It is impossible to state accurately in figures the mortality of heart lesions complicating pregnancy and parturition. So much depends upon so many factors present in each case. The claims of the child must not be overlooked. Disease of the thyroid gland is not to be forgotten in studying cases of the class under discussion.

Proteinic Intoxication from Cow's Milk, and Marasmus.—Gueit makes use of the term atrophisa, or failure to thrive, instead of marasmus, but with the exception of the implied fatality of the latter one term covers the other fairly well. The French pediatricians who employ Parrot's word have usually stated that atrophisa is secondary to chronic gastroenteritis—a gastroenteric cachexia. It is known that in some cases there is retention of urea—uremic atrophisa. Parrot was careful to distinguish his malady from the marasmus of congenital syphilis. Parrot, Marfan, and others have insisted that atrophisa must begin in the first three or four months of life when the digestive secretions are more or less in abeyance, and the organism is poor in defensive forces. This is a period peculiarly favorable for protein intoxication. Since 1833 we have known of the existence of enzymes in milk which are specific for the animal, and presumably alien to the blood of other species. The possibility that these could cause morbidity is greatly weakened by the fact that they are readily destroyed by heat and in sterilized or pasteurized milk they should be inert. The destruction of enzymes as well as of the antiscorbutic vitamin by heat has been one of the great objections to the use of this resource in infant feeding. The injurious protein is not enzymatic in nature, and is apparently heat-stable to a considerable extent. It is only imperfectly attacked by the digestive solutions of the infant, and also is able to make its way through the gastroenteric wall and into the circulation, where it deranges the metabolism. Incidentally it often leads to nitrogen retention, and the picture of uremic intoxication may be recognized among the symptoms. Another disturbance of metabolism is seen in the not infrequent development of acidosis. To the diminution of the alkaline reserve of the body is attributed the lowered resistance to infections of various kinds. In general the condition tends invariably to terminate in marasmus, atrophy, atrophy, wasting, atrophisa, or whatever we choose to term it. The acidosis in these cases is not really primary, but akin to the acidosis of inanition. While it does not cause uremia the inanition aggravates it. The infant cannot handle the protein of the cow's milk because it is heterologous. Not only is it in itself a proteinic poison, but there develops a pathological nitrogen retention. The condition is antagonized in nature by two factors, the child's own digestive enzymes and the enzymes of human milk in the breast-fed.

Clinical Value of Echymsoses.—Brecht states that echymsoses occur in all organs, but only when visible do they have clinical importance. Concealed echymsoses, on the other hand, have value in autopsy chiefly in forensic medicine. They are readily recognized, as the color is deeper in the center and pales out toward the periphery. They show no alteration of appearance on pressure. They always suggest trauma but often appear as if spontaneously. Washing or flushing the

surface will eliminate accidental coloring in certain cases. Of other than traumatic components is increased blood pressure. If this is sufficiently high in the particular tissues echymsoses are bound to result as in asphyxia. Certain neuroses and organic nervous affections, including tabes, alcoholic neuritis, and hysteria, may be attended with their formation. The predisposing influence of blood changes is wellknown and seen in very dissimilar conditions, as hemophilia, scurvy, and sepsis. The relation between the trauma and the site of the hemorrhage may be greatly modified by the locality, notably in the face where an expert may often determine the kind of violence from the shape of the discoloration. Another element is the spread of the extravasation along the loose cellular tissue, long after the violence has been sustained. Thus an extensive echymsosis may suggest a degree of violence far greater than that which actually occurred. The peculiar change of color begins about the third day and the discoloration does not completely vanish before a fortnight. The author goes into much detail in regard to echymsoses in the various parts of the surface and the types due to special kinds of violence.

Aporionerosis.—Austregesilo would substitute this term for the German *Angstneurose*, which he regards as too Freudian for the present state of our knowledge. "Aporio" in the author's term is from the Greek *aporia*, indicating doubt, anxiety, worry, embarrassment, etc. The dominant character of the condition is anguish and anxiety, expressed as pantophobia. While anxiety is a mental state anguish implies physical suffering—a sense of oppression or constriction, presumably of bulbar origin. In the author's practice the two conditions have invariably been associated in the same subject and it is very difficult to determine where one begins and the other leaves off. The condition is physiopsychic, and in addition to the thoracic localization of the principal symptoms there are added many vasomotor symptoms, vascular and secretory. The author cannot subscribe to a universal psychosexual motivation of this affection which is evidently one of his chief reasons for discarding the term *Angstneurose* as employed by Freud and his school. He prefers, in fact, to eliminate this view for the time, while not denying the operation of a sexual factor here and there. The author finds among his aporionerositics married women and men who have ample sexual freedom. Sexual gratification does not prevent crises of neurotic attacks. The Freudian idea leads to the recommendation to indulge in coitus. Naturally the author is opposed to psychoanalysis as a routine procedure, and compares it to the methods and tortures of the Spanish Inquisition.

La Presse Médicale.

March 2, 1921, xxxix, 18.

Angina and Scarlatina.—Mironesco goes into the subject of the exact relationship which subsists between the disease scarlatina and the local condition of angina. In a few cases only, as when the disease is contracted surgically, is there conclusive evidence that angina is purely a secondary manifestation and disconnected with the original lodgment of the causal virus in the tonsillar structures and vicinity. The same sequence has been seen when monkeys are inoculated with scarlatinal virus. The inoculated material came from the deposit in the throat yet could be conveyed by inoculation and in turn cause secondary angina. The latter lesion must be conceived as a sort of reservoir of infectious material which can infect the rest of the organism anew and also spread the disease to others. A perennial source of mystery is the association in an epidemic of scarlatina and simple angina. Does the latter predispose to the former? Or, is the simple angina abortive scarlatina? Attempts have been made in the direction of the serodiagnosis of these simple anginas. The author describes the case of a suspect with sore throat who was practically free from rash, but many streptococci were found in smears taken from the throat.

Book Reviews.

THE OXFORD MEDICINE. By Various Authors. Edited by HENRY A. CHRISTIAN, A.M., M.D., Hersey Professor of the Theory and Practice of Physic, Harvard University, and Sir JAMES MACKENZIE, M.D., F.R.C.P., LL.D., F.R.S., Consulting Physician to the London Hospital. In six Volumes, Vols. I, II and III. New York: Oxford University Press, 1920-1921.

DURING the late war this new system of medicine was undertaken. Owing to changes of concept of medicine, new presentations had to be made. The functional concept to a large extent had replaced the structural concept or had supplemented it. New conditions created by the war changed and modified even this. The progress of research in medicine had become so great that the loose-leaf system was adopted with a view to enabling the possessors of the system to keep up to date and remain in tune with succeeding periods. The activities of American and English men of medicine have been recognized in this work, for they have chiefly contributed to these newer methods. In the system as so far published, emphasis has been laid upon function without neglecting structure, and treatment based upon this has received adequate discussion in its application.

Vol. I is contributed to by twenty-one Americans, one English, one Canadian, and, not least, the late Sir William Osler. Dr. Christian and Sir James Mackenzie write the introductions on Present-day Medicine and the Future of Medicine, respectively, while Dr. William B. Johnston completes the Introduction with the Heritage of Modern Medicine. This volume goes on to deal with the fundamental sciences and the general topics of medicine therewith connected and each contribution bears out the central aim of the work, the emphasis on function as distinct from but allied with structure, and the treatment which belongs thereto. Dr. Albion W. Hewlett presents Pathological Physiology and its relation to Internal Medicine, an able presentation of a very wide subject, even if the title is almost a contradiction in terms. Dr. John J. Mackenzie writes on the living causes of disease and how they act, a subject which is allied to Focal Infection by Dr. Frank Billings and the Mechanism of Bodily Resistance to Disease by Dr. Frederick P. Gay. Indeed, these chapters, like others which succeed on other topics, are arranged so as to form sections—a valuable arrangement. Dr. Donald Van Slyke deals with the Chemistry of the Proteins and their relation to Disease, and no abler presentment could be made. And this chapter is followed by those linked by the subject of Biochemistry on Acidosis and the Physicochemical Equilibrium of the Organism by Dr. Lawrence J. Henderson; on Radiations and their Effects by Dr. William T. Bovie; on Calorimetric Methods of the Study of Disease by Dr. Eugene F. Du Bois; on Respiration in Disease by Dr. Francis Peabody, specially valuable in the light of more recent research; and On the part Played in Diet by Food Substances of Unknown Chemical Nature, by Dr. Elmer V. McCollum, though this latter might possibly be extended in the loose-leaf by more recent researches. Then come chapters on Climate in Relation to Health and Disease by Dr. Henry Sewall; on Aviation Medicine, by Dr. W. H. Milner and Dr. L. G. Rowntree, who later contributes the chapter on The Pharmacological Basis of Medicine. Dr. Charles B. Davenport writes on Eugenics in relation to Medicine, and Dr. William Palmer Lucas on Adolescence. The Rationale of Clinical Diagnosis receives attention from Dr. Lewellys F. Barker, who with irresistible logic emphasizes the need of the Group system, and this is followed by Tests of Function, a subject at the root of the purpose of the system, and receiving treatment from Dr. Christian, one of the editors-in-chief. Treatment of Disease then gets its share at the hand of Sir William Osler. Hydrotherapy and its place gets able attention from Dr. Guy Hinsdale, and three chapters are given to Preventive Medicine in The Prevention and Control of Acute Respiratory Infections by Dr. Joseph A. Capps; on Environment, Its Bearing upon the Maintenance of Health, by Dr. Walter B. James; and on Medical Social Service as a Factor in the Diagnosis and Treatment of Disease, by Dr. Richard C. Cabot. The whole volume is well arranged and conceived as treating the Principles of Medicine. The paper and print-

ing of the volumes are worthy of all praise, the binding is strong and good and should endure the changes which it is proposed to make each quarter-year. Altogether the outside of the volume is worthy of the firm which publishes the work and the subject and plan of the work will enhance the reputation of those who have written it.

Vol. II deals with the Thorax and its diseases; first the Lungs, Pleura and Mediastinum; then the Pericardium, Heart and Blood-vessels, concluding with five chapters on Blood Formation and Destruction, together with the essential blood diseases. Here are twenty chapters divided among twelve American and seven English authors. Dr. Charles F. Hoover writes on Disease of the Bronchi and Respiratory Excursion of the Thorax. Dr. Louis Hamman gives the introduction and general view of Diseases of the Lungs, Lobar Pneumonia and Tuberculosis being reserved for full account in a later volume. Disease of the Pleura and of the Mediastinum are by Dr. Joseph A. Capps and Dr. James Mclester, respectively, while Dr. I. Chandler Walker contributes chapters on Bronchial Asthma and Hay Fever, bringing the subject up to date in regard to sensitization and the relation of anaphylaxis. Diseases of the Pericardium are sagely dealt with by Sir T. Clifford Allbutt. Dr. Ivy Mackenzie writes a full account of The Circulation in Infectious and Toxic Processes, including Acute Endocarditis, and Sir James Mackenzie covers fully, and with common sense, the subject of Chronic Diseases of the Heart; and also, in association with Dr. Girdwood, describes the Diseases of the Arteries, and Aneurysm of the Aorta. Irregular Action of the Heart receives full attention from Dr. John Hay, and Dr. John Thomson covers the ground of Congenital Malformation of the Heart and Large Vessels. Dr. Cecil K. Drinker fully covers the long subject of the pathological Physiology of Blood-cell Formation and Blood-cell Destruction, dealing carefully with the certainties and avoiding the disputed points of research. Dr. George R. Minot enters on the Clinical Discussion of the Anemias, after which Leukemia receives attention from Drs. Thomas Ordway and Whittington Gorham; Polycythemia is discussed by Dr. Reginald Fitz, Hemophilia by Dr. Jay McLean, and Purpura and Allied Conditions receive full attention from Dr. Christian. All the subjects are fully dealt with and the entire volume of 817 pages maintains the character of the issuing publishers, the purpose of the System, and the reputations for careful accuracy of the various authors.

Vol. III covers the Diseases of the Gastrointestinal Tract, Nephritis, and Disturbances Affecting the Supra-nal, Pituitary, Thyroid, and Parathyroid Glands. Dr. Frothingham describes most excellently the Diseases of the Esophagus, Dr. Rehfuess covers all the Diseases of the Stomach with the exception of Ulcer, which is left to Dr. Sippy. In the latter article Roentgenograms and their interpretations are dealt with, although Dr. Rehfuess gives the laboratory findings but does not reproduce the pictures, and a little addition of such pictures would have helped Dr. Frothingham's article. Dr. Stockton in his article on Diseases of the Intestine covers this point and the whole subject thoroughly. Sir Humphry Rolleston gives a well-written analysis of the Diseases of the Liver, Gall-Bladder, and Bile Ducts, and Dr. Joseph A. Pratt deals with the difficult subject of Diseases of the Pancreas. Diseases of the Peritoneum are discussed by Drs. Pincoffs and Boggs, with the recognition that there is no medical treatment for such diseases. One of the chief editors, Dr. Christian, deals carefully and excellently with the subject of Nephritis, giving valuable suggestions for treatment, especially in the illustrative diets. War Nephritis receives attention from Sir John Rose Bradford, and Diseases of the Adrenals and Pituitary is covered by Drs. Riesman and Horrax, valuable contributions to this field of medical science. Dr. Plummer's article has yet to be added. The volume maintains the character of its predecessors.

It is too soon to judge of the convenience of the loose-leaf system in a medical work. If the alterations are made promptly and frequently they will probably be appreciated by those who have no other means of keeping up with the progress of medicine. How it will work out in respect to the Index remains to be seen.

Society Reports.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

One Hundred and Fifteenth Annual Meeting, Held in Brooklyn, May 3, 4, and 5, 1921.

SECTION ON MEDICINE.

(Concluded from page 939.)

Nature of Hypertension.—Dr. HENRY A. CHRISTIAN of Boston presented this communication. He stated that two types of change in blood pressure were recognized, one a transitory rise of relatively little clinical significance, and the other, a persistent high blood pressure which was the one generally understood when they spoke of hypertension or hyperpiesis. In connection with persistent hypertension we must recognize first that there was a very considerable variation in blood pressure in individuals with hypertension. On the whole the individual with high blood pressure was rather more unstable than the individual with a normal blood pressure. If one had a quiet patient and introduced a disagreeable or worrying topic the blood pressure rose abruptly and then fell to its preceding level. He emphasized that point because it served as a warning of the clinical methods of managing these cases. If one realized that the blood pressure was unstable he would not be surprised when it rose or unduly elated when under his methods of treatment there was a fall in blood pressure. The chief factors in increasing blood pressure were as follows: (1) Anything that decreased the peripheral stream or contracted the vessels raised the blood pressure. (2) Any increased output of blood, other factors being equal, raised the blood pressure. (3) Anything that increased the total volume of blood increased the blood pressure. (4) Anything that increased the viscosity increased the blood pressure. Most observers regarded the first as the chief factor in causing hypertension. A small group of observers thought an important factor in increasing blood pressure was increase of the total volume of blood. The cardiac output in its variations was a considerable factor but few had regarded it as a very important cause of hypertension. Increase in viscosity as a cause of high blood pressure had had many adherents but at the present time the majority of observers did not regard increased viscosity as a very prominent factor in increasing hypertension. Thus two of the four chief causes of hypertension were eliminated. Everyone would agree that anything that increased the volume of cardiac output, the size of the peripheral stream remaining the same, the blood pressure would necessarily rise. Then the important thing to consider was what evidence we had that the total volume of blood was increased in patients in whom the blood pressure was above normal. The first evidence lay in the fact that if one fed excessive amounts of fluid the blood pressure rose, and rose particularly in those patients whose blood pressure was above normal. Further evidence lay in observations made on that particular type of acute nephritis common under war conditions, in which the lesion developed rapidly but the patient had little or no edema, the blood pressure rose, and with the rise in blood pressure there was evidence of increased bulk. This increase was due to the fluid rather than the solid constituents of the blood. It was also observed that the subcutaneous tissues took on a tense feeling as though they should be edematous but they did not pit on pressure. When this lesion cleared up the blood pressure and blood volume came to normal. In contrast to this, in chronic types of nephritis the majority of observers had failed to find increase in blood volume in chronic and persistent types of high blood pressure, but rather a decrease in the bulk of the blood. However, methods of measuring blood volume were unsatisfactory and must be accepted with caution. Dr. Christian then discussed the evidence brought forward to show that the increase of blood volume lay in the sodium chloride content of the blood. He reported observations made by Dr. O'Hare on 50 cases of hypertension, one-half of which had more than the normal amount of sodium chloride in the blood and one-

half had less than the normal amount. The results showed that the amount of sodium chloride in the blood did not furnish an explanation of the increase in blood pressure. On the other hand he would not say that sodium chloride had nothing to do with it. Discussing the evidence furnished by therapeutic results of a marked decrease in sodium chloride intake, he said that Dr. O'Hare had come to the conclusion that the blood pressure did not come down much better with decreased sodium chloride intake than with some other forms of treatment, and furthermore, when the blood pressure did come down it had a habit of going up again when the patient was out of the hospital and back in a busy life. The popular belief was that the main factor in increased blood pressure lay in something that decreased the size of the peripheral blood stream by decreasing the caliber of the vessels. This might be caused by vasomotor contraction or vasomotor spasm or it might be brought about by reason of lesions decreasing the lumen of the vessels. The same changes in blood pressure might be brought about in both ways. Lesion in the blood vessels need not necessarily decrease the caliber of the vessels but might affect them so that they did not respond to vasomotor stimuli, and might derange compensatory contraction and dilatation, and thus favor the production of hypertension. Changes in the vessel walls affected more particularly the smaller vessels, arterioles, capillaries, venules. However, arteriosclerosis was not a cause of hypertension nor could it prevent hypertension, but hypertension could cause arteriosclerosis. As to the relation of nephritis to high blood pressure, an organic lesion might interfere with dilatation of the peripheral vessels and bring its force to bear in that way without decreasing the lumen of the vessels. Observations were in agreement with the idea that vasomotor spasm kept up continuously might produce eventually organic lesion. If one accepted that theory one could explain a large number of cases of hypertension. On this theory or a combination of these two factors one could explain why the blood pressure was practically always above normal, and, in addition, why it rose and fell abruptly. He thought all were agreed that the kidney could bring about this change, through its failure to eliminate toxic substances, but it was also quite generally agreed that other factors besides renal lesions might have this effect. Possibly, the internal secretions, but he was rather skeptical on this point as nothing had been definitely proven. He would warn the endocrinologist against explaining high blood pressure by an endocrine disturbance. Infection probably played a considerable part in producing these vascular changes. Possibly sodium chloride did also, but because of its irritating effect on the vessel walls rather than because it drew fluid into the blood stream. Nervous strain must be accepted as another important factor. In concluding, Dr. Christian said that hypertension had other causes than renal insufficiency. Its presence did not make the diagnosis of chronic or acute nephritis; its causes were probably not one but many. The mechanism was probably not the same in each case, but with certain variations lay in changes in the peripheral blood stream. It might be said that increased blood pressure was due to disturbances in the peripheral cardiovascular system in much the same way that we said that fever was an indication of infection, and by the same token hypertension was just as little a disease as was fever. If one assumed that the causes of hypertension were multiple there would be no single way of treating every case, but there would be a variety of therapeutic measures which, if applied to individual cases on a correct basis, would give satisfactory therapeutic results.

Symptoms of Hypertension.—Dr. ALFRED STENGEL of Philadelphia made this contribution, in which he said he took his stand with Dr. Christian in regarding hypertension as a symptom and a symptom commonly due to renal disease. There was also hypertension without renal disease, so-called essential hypertension. There were other cases due to intracranial difficulties, organic or functional, and possibly some associated with disease elsewhere, such as arteriosclerosis, not yet recognized. Dr. Stengel stated that he was not dogmatic in any statement he made in regard to the symptomatology, still there was a certain number of

cases of hypertension that failed to show renal inadequacy. In some cases one could also exclude other organic diseases, and by studying the early symptomatology could arrive at some notion of essential hypertension. These cases were enormously more common in women than in men, and in them the first symptom was fatigability. These patients complained of excessive exhaustion at the end of the day, it being no trifling symptom, but impelling in its seriousness. This was perhaps in essence a nervous symptom. It did not seem to be cardiac fatigue or reflex cardiac fatigue. Many such cases were probably called neurasthenic, in which there was an unrecognized hypertension. There were other nervous symptoms not so important, such as neuralgia of the occiput and upper spine, and extremely severe headaches. Patients complaining of a feeling of pressure behind the eyes, or of tinnitus aurium, also frequently showed hypertension. This was commonly present where there was arteriosclerosis. There might be severe nervous symptoms as temporary aphasia, unconsciousness, apoplecticiform seizures, followed by temporary paralytic symptoms. It was, however, extremely difficult to say that certain cases of apoplecticiform seizures were due to hypertension and not to an actual lesion in the brain. But these attacks of unconsciousness, followed by a little aphasia, temporary loss of power, corrected in a few hours, and disappearing completely, were exactly the same as attacks of ophthalmoplegia in migraine. There was only one explanation for these occurrences and that was some vasomotor disturbance resulting from hypertension, possibly vascular spasm, but when these symptoms persisted it was risky to say that they were due to arterial spasm, though it was possible that in some cases arterial spasm might be attended with convulsive attacks. Dr. Stengel said he had emphasized these nervous symptoms because patients would often have hypertension for a long time without symptoms, and when they began to have symptoms they rarely began with cardiovascular symptoms first, but with symptoms referable to the nervous system. When cardiovascular symptoms manifested themselves they were sometimes in the form of throbbing of the small vessels, but more frequently were referable to the heart or large blood vessels. Some patients suffered from cardiac depression and substernal pain with aortitis. Such symptoms were in part due to hypertension, but no doubt also to actual lesion in the aorta. Vasomotor symptoms undoubtedly occurred early in some cases of hypertension, such as spasm of the small vessels, very largely displayed in the splanchnic circulation. Patients with hypertension showed a remarkable tendency to flushing and pallor, an exaggeration of what one saw in women at the climacteric. Many cases of hypertension might be recognized with the finger on the pulse. One might have fatigue from many causes, or nervous disturbances from many causes, but the accentuation of the second aortic sound and widening of the arch of the aorta rarely occurred unless there was actual aortitis. However, accentuation of the second aortic sound was not always marked. It was only by taking the blood pressure, even if one thought it was low, that definite evidence of hypertension was established. In the early stage of hypertension, before one had a right to assume that there was any renal disease, one did sometimes find a polyuria that could not be explained on the ground of inability of the kidney to concentrate. Hypertension without renal disease differed from hypertension with renal disease. There were a large number of cases of hypertension which would show an enormous pulse pressure, compared with the renal disease, and similarly the blood pressure might be low in comparison with the degree of kidney involvement, but the difference in the systolic and diastolic pressures was much greater in hypertension without renal disease than in hypertension with renal disease. Another point that must be taken into consideration was the dynamics of the heart. Finally one must be very cautious in attempting to attribute to essential hypertension conditions which might be due to renal disease. The existence of hypertension was very easily overlooked if one depended upon physical signs. One should regard especially the aortic second sound and take the blood pressure. A large number of cases of

supposed cerebral disease were probably not due to that condition, but to disturbances of the circulation. Another point in this connection was that authorities called attention to two kinds of uremic convulsions, one of short duration and not accompanied by stupor or somnolence, and a severe type with stupor and somnolence; he entertained the suspicion that the minor cases were not uremic convulsions, but disturbances of the circulation due to hypertension, and were comparable to cases of convulsions due to arteriosclerosis or to hypertension itself.

Treatment of Hypertension.—Dr. W. D. ALSEVER of Syracuse read this paper, in which he stated that there could be no established treatment of hypertension, for it was neither a disease of itself nor a sign of a single malady. Many people believed hypertension was a disease and expected direct action against it. Blood pressure readings should not be told to patients. Actually hypertension was a desirable compensatory factor in a vicious circle, and the cause being controlled, the pressure should not be disturbed except in real emergencies. Transient hypertension was often of little consequence, was evidence of nervous instability, and in itself called for no treatment. Mild hypertension lasting a few days and relieved by rest or elimination was of great importance. It suggested the early and perhaps curable stage of some disturbance which, if allowed to continue, might cause persistent hypertension and lead ultimately to death. All hypertension called for searching investigation into the underlying cause. Routine yearly examination of people over forty had great prophylactic value. The part of complete examination most neglected in modern practice was history taking. The taking of the history by the doctor himself was an important part of the treatment of hypertension. The family history must be carefully studied. The functioning of every system in the body must be carefully inquired into. One must obtain an intimate knowledge of the patient's pleasures and troubles, his habits and tendencies, even to knowing what, how much, and how he ate, how much he slept, and when and how much he played. All sources of metabolic errors must be controlled. These were perhaps the most difficult to treat of all the causes of hypertension. Under this head came regulation of food and drink, of the motility of the intestines, evacuation of the bowels, and the amount and quality of the urine. Emphasis was laid on the proper mastication of food and making of meal time a period of mental recreation and physical rest. The quantity of food taken was more important than the kind. With hypertension, 25 or 30 calories per kilogram of body weight was often sufficient. It was desirable that the patient be kept at from five to twenty pounds below his optimum weight in health, but inanition must be avoided. Any excess of flesh was to be controlled through restriction of food or through occasional purging and fasting. Two compound cathartic pills at night and the omission of the next three meals would frequently be followed by a fall in blood pressure, a noticeable relief of associated symptoms, and a loss in weight. Protein should be limited to the necessary amount for good nutrition of the cells of the body; one gram per kilo of body weight was usually the desirable amount. Part of the protein might be and probably should be in the form of meat. The color of the meat was of no practical importance, excepting that red meat was desirable if the patient was anemic. It was wise to eliminate extractives, as meat broths and **gravy**, condiments, and all glandular foods, as they put an unnecessary burden on the kidneys. Foods difficult of digestion should be restricted. A sample menu was presented which furnished approximately 70 grams of protein and 2000 calories. It was made elastic, for the object was to develop the habit of eating moderately of well-balanced wholesome menus. Sufficient water should be available for the various chemical processes, and for the solution of food and waste products, which must be transported from place to place. Unless the kidneys were defective enough water should be taken to keep the quantity of urine above 1500 cc. and the specific gravity below 1020. The patient's days should be regulated so that he led an uneventful life. Each day there should be at least eight hours sleep, induced if

necessary. That hypertension patients should be told once how to regulate their lives was not sufficient; the doctor must frequently review in detail the patient's daily routine. When, after thorough treatment it became evident that hypertension was permanent, the therapeutic problem became one of maintaining compensation and avoiding complications. All the treatment suggested for transient hypertension applied with added force, and some additional measures were indicated. Lower caloric values of diet for short periods might be useful, as more frequent and prolonged periods of starvation or the milk diet of Karell, accompanied by rest in bed, and limitation of protein below 1 gram per kilogram of body weight, or even total abstinence from protein, might be tried when there was nitrogen retention. The quantity of salt should never be excessive, perhaps not more than 2 grams per day, but its limitation must depend upon the kidneys' ability to secrete it. A safe, practical rule was to give no more water by mouth than was excreted as urine and fluid stool. If sufficient water was not taken by mouth, rectal injections or Murphy drips of saline, soda, or glucose solution would supply water to the body and also wash the lower bowel. Continued watery catharsis was of doubtful value. Occasional bouts of diuresis were of value if the kidneys were still competent. The withdrawal by needle of 300 to 500 c.c. of venous blood was usually salutary and harmless. In general, exercise was to be continued in sufficient amount to maintain muscle tone, but should not be carried to the point of exhaustion. Mental overwork was more to be dreaded than physical fatigue. Psychotherapy should not be neglected. Water, air and light baths, and massage treatments were valuable if they soothed the nervous system and favored elimination. Extreme degrees of temperature and prostrating treatment should be avoided. Wool should be worn next the skin when the patient was exposed to the abrupt changes of the temperate zone. Iodide of potassium given because of its supposed ability to aid in the elimination of abnormal substances or to diminish the viscosity of the blood had but slight effect; aconite, usually the tincture, 5 minims or more, every four hours, was the best drug for maintaining blood pressure at a lowered level. However, its use was rarely justified except in emergency. The nitrites caused a temporary lowering of the blood pressure, and served to emphasize the fundamental therapeutic principle that drugs must be repeated before the end of their physiological action if sustained effect was to be produced. Nerve sedatives should be given steadily. The high frequency or d'Arsenval current would diminish hypertension, and was useful in emergencies, but it should not be used as a substitute for regulation of the patient's life. Radium was also said to lower blood pressure. As yet there was no reason to believe that functional disturbances of the endocrine system depended on causes other than those already suggested as influencing arterial pressure, consequently one should regulate the underlying causes of disturbed metabolism rather than attempt to dominate the mechanism through which the cause made itself evident. In the prevention of hypertension moderation in all things should be the guide.

Dr. ELI MOSCOWITZ of New York limited himself to the discussion of Dr. Christian's paper. He said that for years he had been trying to correlate the symptoms of hypertension with the pathological findings. Some years ago he had come to the conclusion that hypertension was not explainable by anatomical data alone, in other words that arteriosclerosis and nephritis alone could not explain hypertension, since the degree of hypertension bore no definite relation to the degree of arteriosclerosis or of nephritic involvement. It was only by clinical observations that he was enabled to find an explanation of the problem. If instead of starting with anatomy one started with function one could arrive at a more satisfactory explanation. All evidence seemed to show that hypertension was the actual cause of arteriosclerosis. If one accepted that thesis as valid, how was he going to explain the kidney lesion? He thought it could be explained on the identical ground. We must regard the kidney disease not as a disease of the organ but as a focal manifestation of a general arteriosclerosis.

It was a vascular lesion in the glomeruli. This conception implied the recognition that arteriosclerosis should not be conceived of as a disease of the larger vessels, but of the small vessels and the capillaries. If one said the kidney lesion was a local manifestation of a general condition, why were not the capillaries of other organs affected? The answer was that they were, but it was difficult to show it. Weiss, however, in 1916, devised a method by which the capillaries in the finger could be observed under the microscope. By this method the remarkable fact was shown that the changes in the capillaries were different in different diseases. In nephritis and arteriosclerosis there was a narrowing of the capillaries. Here was the missing link to show that nephritis and arteriosclerosis were due to one and the same cause, which was hypertension. What was the cause of hypertension he did not know, that was so far as the physical and mechanical causes were concerned, but he suspected they were of nervous origin, due to the stress and strain of life, the ambition to succeed, and forgetting how to play. In the treatment of hypertension the essential point was the reduction of the patient's weight. The tables for weights and heights were all wrong; they were too high. Psychology also had an important function; these patients must be taught the value of play.

Dr. ERNST BOAS of New York discussed recent experimental work showing the importance of the capillaries in producing hypertension and general circulatory disorders, referring to observations made on the capillaries by means of Hooker's microcapillary chronometer. These observations had shown that the capillaries were susceptible to vasomotor influences and nervous stimuli and reacted to mechanical reagents. It was reasonable to believe that such influences prolonged would produce anatomical lesions. It had been shown that histamine injections produced capillary paralysis. This and other experimental work indicated that in the future hypertension and other circulatory disorders would be investigated by a study of the capillaries. Another point of importance was the recognition of the variability of blood pressure, both in the normal individual and in the individual with hypertension. This would save the physician from attributing a change in the blood pressure to therapeutic procedures without very definite evidence as to the effect of such procedures. Owing to the great variations in systolic pressure the relation of the systolic to the diastolic pressure as indicated by the pulse pressure gave more reliable information. If a patient came with nephritis and hypertension, with a decrease in pulse pressure, and a gallop rhythm heard at the apex, it signified impending myocardial failure, and it was here that digitalis was of the greatest value.

Dr. FENTON B. TURCK called attention to work he had done far back as 1893, showing that vascular changes were due to cellular autolysis. He had been successful in producing a serum which stimulated antibodies in the body of the patient against the products of tissue autolysis. This serum injected over a period of months would produce regeneration in the kidney and a lowering of the hypertension.

Dr. LOUIS FAUGERES BISHOP emphasized the point that arteriosclerosis was not a primary disease and said this was something he had been teaching for many years. He wished to emphasize it because it was a matter of much clinical importance. He also emphasized the fact that hypertension was a purposeful thing. It was a matter of adjustment. He believed hypertension was always compensatory, though we might not always be able to explain the mechanism. He did not think it was a matter of blood volume because the circulation was able to hold two or three times as much as it was ever called upon to hold. The idea of a mechanical cause of high blood pressure was to his mind absurd; it was a nervous reaction. It was a foolish thing to reduce the blood pressure as such, and he did not think the physician of today attempted to do that. His idea of treating high blood pressure might be said to be condensed to the use of castor oil, a low diet, and outdoor exercise; the removal of worry did a great deal. The excessive use of saline purgatives was to be decried, because it caused secondary anemia and interfered with normal

intraabdominal pressure; for that reason he used castor oil and some alternative vegetable laxative.

Dr. WARD CRAMPTON of New York City said it was refreshing to hear that blood pressure was a symptom and not a disease; it was his opinion that progress would be made by working with that conception. He had come to regard cardio-renal symptoms, arterial symptoms, and blood pressure symptoms as a group of things that cropped up singly or two or three at a time, and if one investigated these things he would find they all came from the same general state; they were all caused by anti-regimental things, too much work, too much worry, or too much of anything. He had found very pronounced cases of arteritis and whipcord arteries in young people, having seen this condition in a boy of ten years and in another of eighteen years. He had found arteriosclerosis on the right side and not on the left side. There was often a great difference in the blood pressure when the patient was standing and lying down. No examination should be considered complete unless the blood pressure was taken in both the standing and the recumbent positions.

Dr. SELLIAN NEUHOF of New York expressed the opinion that, unless there was definite evidence to the contrary, there might be such a thing as functional hypertension, because in the course of his practice he had followed for a very considerable period of time patients in whom there was no clinical evidence of disturbance of the cardiovascular system or other organs, and no change in the eye-grounds or cerebral arteries. He also spoke of a small group of middle-aged, rather obese people, who had high blood pressure, which he called cases of cardi-spasm; in these a simple regulation of the diet and atropine served to bring the blood pressure down, and it remained normal unless a new dietetic insult was added. The only way in which to pick out the cases of simple hypertension was by exclusion, by laboratory tests, by the x-ray, and by taking a careful history, and that applied not only to cardiovascular disease, but to every other disease.

Thursday, May 5—Third Day.

Intermittent Spasm of the Renal Artery, With Report of Two Cases.—Dr. MEYER A. RABINOWITZ of Brooklyn read this paper and presented two patients. He stated that angiospasm might be caused by arteriosclerosis, and that the reverse was also true. He called attention to the fact that intermittent spasm of the small blood vessels of the eye might cause temporary blindness, and explained the way in which spasm of the small arteries affected different viscera. Spasm of the renal artery might cause very severe renal disturbance during life, and yet no pathology be shown at postmortem. The first patient presented was an elderly woman who had had incomplete anuria for three days and complete anuria for four days. She had had occasional abdominal cramps, but practically no symptoms. She was not a hysterical woman. Her eye-grounds showed slight arteriosclerotic changes; her heart was slightly enlarged; the aortic second sound was not accentuated. The diagnosis was bilateral spasm of the renal arteries. The blood pressure was systolic 215, diastolic 104. Under treatment the blood pressure dropped to systolic 175, but later rose again. She had three or four similar attacks of anuria, and learned that by taking nitroglycerine the capillaries would relax and the attack be relieved. The second patient was an elderly man who, five years ago, was seized with sudden blindness which lasted for about an hour and then disappeared. The eye-grounds were perfectly normal. The systolic blood pressure was 130, diastolic 88. He complained of precordial pain and lumbar pain. He had marked arteriosclerosis affecting many blood vessels. He gave a history of arterial spasm affecting many parts of the body. He had had attacks of partial anuria and his case was diagnosed as one of unilateral spasm of the renal artery.

Dr. LOUIS FAUGERES BISHOP said this paper should not pass without discussion. It was certain that spasm of the renal artery did happen under a good many different circumstances. He stated that he had seen a case recently due to digitalis poisoning. Someone in trying to slow a rapid pulse, in which there

was no specific irregularity, had given much more digitalis than was wise. The patient had developed edema of the lower extremities and other evidences of digitalis poisoning. He had not passed much urine in several days. The digitalis was stopped and the vasomotors dilated. The man then passed about 200 ounces of urine in an hour. Evidently a spasm of the renal artery had been produced by digitalis. The reader of the paper had spoken of congestion as a cause of anuria; he was prone to attribute anuria to congestion rather than to anemia.

Points of Contact Between Some Surgical Conditions and Cardiac Disorders.—Dr. SAMUEL A. LEVINE of Boston, Mass., presented this communication in which he discussed some conditions having certain surgical features concerning them, but in which a disturbance in the heart was playing a significant rôle. He described several cases which he had seen in which the clinical picture pointed very definitely to an acute surgical abdomen. The history in these cases was sudden, severe pain in the upper abdomen, associated with nausea, vomiting and collapse. When seen these patients had marked pain in the epigastrium, between the naval and the right costal margin, and also in the gallbladder region. There was spasm, and rigidity of the abdominal muscles in this area, and it was suspected that a tumor mass could be felt in the right costal margin, which might have been gallbladder or liver. The temperature in these patients was about 102° and the leucocyte count over 20,000. The rest of the examination was essentially negative, except that the heart sounds, though regular, and only slightly rapid, were quite distant. This point was particularly striking, because the intensity of the first sound at the apex was diminished more than the second. The systolic blood pressure was low. These cases suggested that it was not at all unlikely that some of the patients operated upon for gallbladder disease or gastric ulcer, in which the surgeon found no abnormalities, might be explained on this basis. It was important to bear in mind the possibility of coronary thrombosis with cardiac infarction in patients presenting the picture of acute upper abdominal disturbance when it occurred in patients over forty years of age. An entirely different type of cardiac patient which might present a perplexing problem to the surgeon was that in which there was auricular fibrillation or delirium cordis. As an illustration of this type of cases Dr. Levine cited the case of a middle-aged woman who entered the hospital with acute pain in the gallbladder region of sudden onset; also abdominal pain, nausea, vomiting, jaundice, slight fever, marked tenderness in the gallbladder region and yellow sclera. She was operated upon for gallstones and none found. She had a similar attack two years later. The first attack probably resulted when her heart, which had previously been well compensated, developed the new rhythm of auricular fibrillation with the accompanying rapid ventricular rate. She recovered from the first attack, while with the second attack the auricular fibrillation became permanent. Mention was made of instances in which the presenting symptoms were those of acute appendicitis, but which subsequently proved to be pericarditis. This was probably a rare occurrence. Of possible help in the diagnosis of such cases would be careful auscultation of the heart, listening to the heart with the patient in different positions, and with the patient's chest inclining forward. An entirely different set of circumstances might lead the surgeon to call for advice, namely, if the heart had some queer upset during or following operation. These disturbances were generally included in the term paroxysmal tachycardia and might take on the form of auricular tachycardia, auricular flutter, or auricular fibrillation. The writer cited three cases of the first type in which the attack was immediately arrested by vagal stimulation. Two patients during the early stage of convalescence after operation had attacks of paroxysmal auricular flutter and five had paroxysmal auricular fibrillation. All the patients in these two groups responded well to digitalis therapy. Possibly with a closer cooperation between the surgeon and the internist the incidence of these upsets would be found greater than was generally thought. The surgeon often asked whether a

cardiac patient could stand operation. Most cardiac patients stood operation very well. There was no available study to show which type of cardiac patient was apt to do poorly. For the present it was probably safe to say that patients with evidence of conduction difficulty in the heart might be subject to sudden calamity during anesthesia, and that all other cardiacs not markedly decompensated would do satisfactorily. A much more important decision for the clinician to make was not whether the patient suffering from cardiac disease could stand operation, but whether the operation was indicated. The possibilities of error in diagnosis brought out in the paper must be borne in mind and the ultimate prognosis of the patient from the cardiac point of view should influence the decision.

Diagnosis of Myocardial Disease.—Dr. HAROLD E. B. PARDEE of New York made this presentation, which was illustrated by lantern slides. He stated that the difficulty encountered in attempting to make a diagnosis of myocardial disease and the frequency with which this diagnosis was made upon a wholly improper and insufficient foundation had led him to attempt an analysis of their methods of making a diagnosis of myocarditis so as to suggest, if possible, how it could be made more surely. To show how very wrong even the best practice might be he quoted the figures of Dr. Richard Cabot from the Massachusetts General Hospital where, of 59 cases that came to autopsy, 22 per cent. were diagnosed during life to have chronic myocardial disease, and were found to have it at autopsy; 52 per cent. were diagnosed to have it, but autopsy showed that it was not present, while 26 per cent. were found to have a chronic myocarditis at autopsy which was not diagnosed during life—78 per cent. of error. This diagnosis was made on certain symptoms and physical signs for the most part in no way specific for myocardial disease. These symptoms were sense of easy fatigue, dyspnea on exertion, slight or moderate, precordial pain, edema about the ankles, chronic cough. Obviously these symptoms were those of circulatory insufficiency and said nothing as to the cause of this. The physical signs were enlarged heart, irregularity, weak first sound (valvular quality), weak, diffuse apex beat and systolic blow at the apex and gallop rhythm. Neither did these physical signs depend wholly upon myocardial disease; they might arise from cardiac failure of any origin. For a correct diagnosis these symptoms and signs must be found in certain combinations, and at the same time one must be able to exclude certain other conditions which might cause them. For instance, if chronic pulmonary tuberculosis was present the dyspnea on exertion could not be attributed to myocardial disease, nor could precordial pain in the presence of aortic aneurysm. In the presence of high blood pressure an enlarged heart did not mean myocarditis, nor did a weak first sound in the presence of emphysema. But if a patient did not have valvular disease, or increased blood pressure or pulmonary disease, and complained of dyspnea on ordinary exertion, had an enlarged heart with valvular quality to the first sound, then in all likelihood he had a diseased myocardium. And yet Cabot's figures were obtained on just this sort of evidence. Nor could tests of the ability of the heart to perform work, as shown by blood pressure reactions or by the responses to exercises be properly applied as a test of the heart muscle's integrity. These tests showed very well the patient's ability to respond to exercise, but there were many other things than heart muscle concerned in this response; the valves, blood pressure, nervous system adiposity, presence of febrile or wasting diseases, etc. Of late years a new sign of myocardial disease had been brought forward in the electrocardiogram record. Variations in these records were coming to tell us more and more about the contraction of the muscle fibers of the auricles and ventricles. To understand the theory of the electrocardiogram was not necessary in order to understand these records. Dr. Pardee then showed normal and abnormal electrocardiograms, and the myocardial condition that usually caused the abnormality of the record. They had learned but little, relatively, about the auricular muscle from variations in the auricular wave P. This had been very little studied.

The ventricles were the important blood-driving muscles. Notching or slurring of the QRS group in two or more leads depended upon either a diseased condition in a large focal area of the myocardium or one affecting a considerable number of the branches of the Puckinje network beneath the endocardium. It was usually a disease of some extent and, therefore, appreciably diminished the functional efficiency of the ventricles. An increased duration of the QRS wave could arise from the same cause, and so, often, notching and increased duration were found together. An abnormal T or T₂ wave was due to an abnormal character of the ventricular contraction, and might be caused by the same disease that caused notching, or by a diffuse myocardial disease that did not cause notching of the QRS wave, or it might be due to poisoning of the muscle as by uremia or digitalis. After a branch of the coronary artery had been stopped by a thrombus or the artery excessively narrowed by disease one might find a peculiarly characteristic downward curve to the T wave of lead three or lead one, and that of lead two would also be turned downward. This was not found in all patients who had precordial pain or discomfort, and therein lay its importance, for those who showed it had an area of heart muscle that was scarred. This remarkable change in the record was not always as serious as it was remarkable, but it was usually serious enough, being due, as a rule, to a diffuse process involving the endocardium and the myocardium in a chronic sclerotic degeneration. Other records showed four typical features: (1) The direction of the QRS wave opposite in leads one and three; (2) notching of the QRS group; (3) wide QRS group (0.14 or more); (4) direction of T wave opposite to largest QRS excursion. Some of the curves had nothing of the QRS group and very small excursions of the waves. These were from hearts that had a similar pathology to those giving the larger waves of the last picture, but the disease was probably more extensive. Sometimes records were obtained in which the waves of the ventricular QRS and T groups were very small in size, and yet there was not notching of the QRS or increased duration, though the T wave was usually abnormally inverted. These were waves of hearts that had a diffuse pathology, and with improvement in the patient's condition these waves would sometimes increase in amplitude. Sometimes they did not so increase, and hearts of this group that he had seen at autopsy showed a diffuse fibrosis, but not one involving the subendocardial layers. When any of these changes were present one could feel quite certain that the ventricular muscle was diseased. The different abnormalities of the record were not so much the result of different degrees of myocardial involvement as they were of different location of the process. The question, what one was to say when all these abnormalities were absent, could only be decided finally by an immense amount of autopsy work. He felt, however, that when a heart did not show some of these abnormalities there was but a minimal amount of disease in the ventricular muscle, not enough to cause symptoms, if it were the only abnormality present. This method of examining the heart in conjunction with the older methods should serve to correct their clinical diagnosis of myocarditis and to reduce some of Dr. Cabot's 52 per cent. or more of error, due to diagnosing myocarditis when it was not; it might also discover some of Dr. Cabot's 26 per cent. in whom the clinical diagnosis was not made, though the heart muscle was found diseased.

Tuberculosis of the Pericardium.—Dr. WILLIAM W. MACLACHLAN of Pittsburgh, Pa., read this paper, in which he stated that the pericardium, situated as it was in proximity to the common site of primary foci of tuberculosis in the thorax, did not present evidences of this disease as often as one would expect. On the other hand, there was little doubt that many of the clinical types of the disease were not diagnosed. From the pathological aspect there was a considerable group of old healed fibrous lesions found at autopsy which were at times not unlikely tuberculous, but as to their exact nature it was a difficult matter to speak positively. Osler, in 1893, described seven cases of tuberculous pericarditis which he had observed either in autopsy rooms or wards, and no essential facts had been

added to his observations. The seropurulent type was probably the more common, though one found also a typical tuberculous exudate which seemed to be more of the plastic type. One could by no means include all lesions produced by the tubercle bacillus in the pericardium in the above mentioned types; there was a large group called the adherent or obliterative pericarditis in which undoubtedly a certain number of cases represented the healed stage of a tuberculous process. Calcification, a cardinal symptom of healed tuberculosis, when it occurred in the pericardium, rarely meant this disease. After reviewing the incidence of tuberculous pericarditis as found at autopsy by a number of observers, the writer analyzed 1000 records from D. Oscar Klotz's department at the University of Pittsburgh with reference to pericarditis in general. His findings in this series were in close agreement with those of other observers. There were 10 cases that were frankly tuberculous, nine male and one female. There were no cases in the first decade of life and only one in the sixth decade. The remaining cases were evenly distributed among the second, fourth and fifth decades. Of the debatable tuberculous cases there were 40 instances of chronic fibrinous adhesions in the pericardial sac; of these 23 were totally and 17 partially adherent. Of these cases three were undoubtedly tuberculous and five probably so. There was definite evidence to indicate that spontaneous healing of the tuberculous process in the pericardium undoubtedly occurred, probably more often than had been imagined. Their material also indicated that the development of lesions on the pericardium had little or no relation to the extent of the tuberculous in other parts of the body. It was surprising to find but three cases of tuberculous pericarditis among 23 cases of general miliary tuberculosis. Acute fibrinous or serofibrinous tuberculous pericarditis was probably the only clinical form of the disease that might be recognized, as it was an entity in the same way as the well-known types of tuberculous peritonitis. The writer had followed two cases of tuberculous pericarditis to autopsy. The history and physical signs and the course of these cases was comparable in general with the description given by Osler. The picture was similar to that seen in acute fibrinous or serofibrinous infections, the rheumatic fever group of diseases, namely, pain, dyspnea, cyanosis followed by the development of a pericardial friction sound. The increase in cardiac dullness was often pronounced. If the fluid accumulated slowly there might be little apparent discomfort. These signs were all compatible with nontuberculous pericarditis; a persistence of the signs beyond the period when it was usual for the ordinary form of acute pericarditis to subside was of considerable value in the diagnosis. During a prolonged course of two to four months one might recognize the pericardial rub often widely distributed. In the writer's cases the pulse was rapid, respiration increased, and the temperature was of the tuberculous type. It was his impression that tuberculous pericarditis which produced a recognizable clinical entity was a disease with a high mortality. Pericardial puncture had the value almost of an emergency measure in relieving the heart and lungs, particularly where the fluid had developed suddenly. Thayer suggested that cyanosis, dyspnea and irregular pulse, with fluid present in the pericardium, furnished the indications for puncture of the pericardium. In the more chronic effusions might be removed in order to promote absorption and prevent reaccumulation. There were some cases, however, in which there was an enormous amount of fibrin and very little fluid, and in these pericardial puncture would yield a dry tap.

Dr. SELIAN NEUHOF of New York considered the point brought out in Dr. Levine's paper in reference to the need of cooperation between the physician and the surgeon in dealing with cardiac cases. There was a definite correlation between the cardiac and abdominal symptomatology, as was well known to those who saw many cardiac cases. It had been pointed out in the literature that a great many cardiac cases had epigastric distress which could be definitely correlated with their cardiac condition. A considerable number of cases of auricular fibrillation suffered very much from gastric disturbances, most of which were due to gas and pressure and were relieved by proper medi-

cation, which usually meant digitalis. Following the proper use of digitalis the digestive disturbances cleared up very rapidly. The cases Dr. Levine had referred to were the more aggravated forms of such gastric disturbances. He had seen in the course of years similar cases, and his observation was correct when he stated that these cases were often incorrectly diagnosed. Likewise his observation with reference to paroxysmal tachycardia during narcosis was correct. He had seen three cases of the type referred to die. He cited one case somewhat in detail in which vagus pressure and all other measures were tried without avail, and this patient died. In these conditions there was a difference whether one was called in early or when the paroxysmal tachycardia was well established. The patients of this kind that died usually developed cardiac dilatation, but the dilatation was not the primary thing; where it occurred it might be assumed that paroxysmal tachycardia had continued for a certain length of time. As for Dr. Pardee's paper, he made a very important distinction between myocardial insufficiency and myocarditis. Myocardial insufficiency by no means spelled myocarditis. He fully agreed with Dr. Pardee as to the importance of electrocardiographic studies, though he was not quite as enthusiastic in regard to the interpretation of electrocardiograms. It had not been his experience that a slight notching of the QRS wave in itself was definite evidence of myocarditis. He still thought we should stick to the term electrocardiographic preponderance rather than electrocardiographic hypertrophy. His experience would also negative the statement that deviation of the T wave in the third lead was in itself evidence of auricular hypertrophy.

Dr. LOUIS FAUGERES BISHOP of New York said he had been talking with Dr. Bennett, the dean of anesthetists, and he had stated that a fibrillating patient unwisely prepared for operation by over-digitalization was a very bad operative risk; the patient might better be under-digitalized than over-digitalized when he came to the operating table. He thoroughly agreed with Dr. Pardee as to the importance of the electrocardiograph and advocated its use in every serious heart case. He deserved credit for having pointed out that the abnormality of the T wave indicated myocardial danger. Dr. Bishop stated that he was so enthusiastic in regard to what one could learn from the electrocardiograph and what could be done for cardiac patients, that he had started a model cardiac clinic at the Good Samaritan Dispensary where the ordinary cases of cardiac disease would be carefully studied, because he felt that we were short in our knowledge of cardiac disease, and had given too much attention to the rare cases and not sufficient study to the ordinary type of cases.

Dr. LEVINE felt that the figures quoted showing a large error in the diagnosis of cardiac cases at the Massachusetts General Hospital could be explained by the fact that the term myocarditis was used rather loosely, and thought the figures from other clinics would make no better showing. He said that many cases died of heart failure and yet the pathological examination showed nothing. Many cases of chronic myocarditis showed nothing at autopsy and he had seen cases of extensive myocardial disease which gave normal electrocardiograms; the T waves were all upright. He thought they must not be led astray by the idea that the electrocardiogram would tell everything. It added a great deal and was an aid, but one must not be carried away by too much enthusiasm.

Dr. ALFRED MEYER said that in dealing with acute paroxysmal tachycardia he had been disappointed by pressure on the vagus. The method which had succeeded in his hands in several instances was the administration of morphine; digitalis was valueless. He agreed with Dr. Levine as to the frequency with which their colleagues failed to recognize right-sided angina pectoris, and mistook it for gallstones. With reference to Dr. Pardee's figures, he said he was sure Dr. Levine's feelings would be soothed if he inspected the records of the New York hospitals and saw the frequency with which myocarditis was diagnosed. Immediately when an irregularity of the heart action was discovered it was put down as myocarditis; they did not even say myocardial degeneration. Speaking of Dr. MacLachlan's paper, Dr. Meyer referred to observa-

tions made by Dr. Warthin, who found tuberculous lesions in the liver in an unusually large percentage of cases of miliary tuberculosis and not even recognized at autopsy. A more thorough study of pericardial adhesions might show that a considerable number were due to tuberculosis. The electrocardiograph was a help in the diagnosis of cardiac disease but not in the therapy. He would make a plea for the use of the x-ray at the bedside. With reference to the treatment of pericardial effusion, especially in tuberculous pericarditis, Dr. Meyer stated that three or four years ago he had made a plea before the American Medical Association for the employment of pneumopericardium. He had been the first to use it in the United States, but the method had not had as extensive trial as it deserved. He felt that the method had a definite future in the treatment of pericarditis with effusion.

Transient Myelosis in the Course of an Acute Infectious Disease.—Dr. SIMON R. BLATTEIS of Brooklyn reported this case, which occurred in a man 45 years of age, giving a history of a recent influenza and possibly endemic typhus. The leucocyte count reached as high as 100,000, the myelocytes 48 per cent., and the eosinophiles from 10 to 14 per cent. The enlarged spleen and liver and other findings seemed to point to a myelogenous leukemia. Later the blood count returned to approximately normal. The study of this case led to the conclusion that many so-called cases of leukemia were after all only cases of infection presenting an unusual leucocytosis, though it was possible that an early myelogenous leukemia might be set in motion by an acute intercurrent infection.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held March 28, 1921.

THE PRESIDENT, DR. GEORGE GRAY WARD, JR., IN THE CHAIR.

Symposium on Pneumonia.—Etiology of Pneumonia.—Dr. RUSSELL L. CECIL made this contribution, in which he stated that when a physician had made a clinical diagnosis of pneumonia, there were several questions which immediately presented themselves for solution: 'Is it a primary pneumonia, or is it secondary to some preexisting pathological condition? Is it lobar or bronchial pneumonia? How many lobes are involved?' 'Finally, and in some respects the most important question of all—Which of the various bacteria are responsible for the infection?' Dr. Cecil said he was aware that many clinicians would disagree with him on the relative importance of the bacteriology of pneumonia, while, strangely enough, these same clinicians would admit the necessity for bacteriological information in other infectious diseases. He thought there were two reasons for a lack of interest in the bacteriology of pneumonia: First, because the bacteriology of pneumonia had been one of the last branches of this subject to be worked out accurately; secondly, because there had been no specific treatment for pneumonia. Neither of these reasons, however, held good at the present time. Then, too, the prognostic value of bacteriological diagnosis in pneumonia had not been sufficiently emphasized. In respect to prognosis the microorganism present had great significance. For example, *B. friedlander* pneumonia was nearly always fatal. The mortality rate in pneumococcus pneumonia varied greatly with the type. A similar divergence was found in streptococcus pneumonia. The figures of Lochez and Gillespie at the Rockefeller Institute gave the rate for pneumococcus Type III pneumonia as high as 50 per cent., while pneumococcus Type IV showed a rate of only 10 to 15 per cent. *Streptococcus emolyticus* pneumonia had a death rate varying from 0 to 60 per cent.; whereas *Streptococcus viridans* pneumonia was one of the mildest forms encountered, lying under 10 per cent. in the Camp Upton series. From the figures it appeared that in many instances the type of bacterium present had a more important bearing on the prognosis in pneumonia than either the character or the extent of the consolidation. Practically speaking there were only three bacteria that were

commonly concerned in the etiology of pneumonia,—pneumococcus, streptococcus, and *B. influenzae*. Friedlander's bacillus, *Staphylococcus aureus*, meningococcus, and other microorganisms were occasionally responsible for this disease, but they constituted such a small percentage of the whole that they must be looked upon as rarities. The pneumococcus was the usual cause of lobar pneumonia. In a study of the various types of pneumococci, the fixed types were found to be responsible for about 80 per cent. of all lobar pneumonias, the remaining 20 per cent. being caused by Group IV strains. The streptococcus was the organism most frequently found in bronchopneumonia. Here again we must classify into "hemolytic" and "viridans" groups. It should be emphasized that both types of streptococcus pneumonia occurred as a complication or sequel to some preceding disease or injury. During the war the hemolytic streptococcus attained such a high degree of virulence that it appeared in some instances to excite a primary pneumonia, but such cases were exceptions to the rule. The influenza bacillus also produced a characteristic type of pneumonia, best exemplified by the nodular hemorrhagic pneumonias so frequently seen during the big epidemic. *Staphylococcus pneumoniae*, like *B. friedlander* pneumonia, was usually fatal. In discussing the mode of infection the essayist stated that recent experiments indicated that lobar pneumonia was bronchiogenic rather than hematogenous in origin. The constant production of the disease in monkeys by intratracheal injection and the constant failure to produce it by subcutaneous or intravenous injection were believed to be conclusive evidence that infection in lobar pneumonia took place not through the blood stream but by way of the respiratory passages. The hematogenous theory had apparently depended upon the clinical observation of cases in which the pneumococcus was known to be present in the blood at the time of onset of clinical symptoms of pneumonia, or in occasional instances before the clinical symptoms of pneumonia had appeared. The interpretation of this observation as indicative of the hematogenous origin of pneumonia was incorrect; this was established by the fact that in pneumonia experimentally produced by the intratracheal injection of pneumococcus, the organisms had appeared in the blood stream within six to twenty-four hours after injection, frequently before clinical evidence of pneumonia or elevation of temperature had developed. The spread of pneumococci in the lung in lobar pneumonia was by way of the perivascular, peribronchial, and septal tissue and lymphatics, the alveolar structure was primarily infected by spread of the pneumococcus from the grosser framework of the lungs into the alveolar walls. Experiments with the *Streptococcus hemolyticus* on monkeys indicated that the mode of infection in streptococcus pneumonia was similar to that in pneumococcus pneumonia. The reaction of the tissues to the streptococcus was different and therefore the pathological picture was different, but the mode of infection was apparently the same. With the influenza bacillus, a different mechanism seemed to be at work. The influenza bacillus lacked the invasive character possessed by the pneumococcus and streptococcus, consequently the lesions produced by this organism were local while those produced by pneumococcus and streptococcus involved extensive areas. The influenza bacillus injured chiefly contiguous parts, probably by means of toxic substances which it secreted. Referring to the epidemiology of pneumonia, the United States Census for 1900 showed that more than 10 per cent. of all deaths were due to some variety of pneumonia, and statistics seemed to indicate that the incidence was increasing. During the past few years important studies on the epidemiology of pneumonia were carried out at the hospital of the Rockefeller Institute. In a study of 297 normal individuals, Type I and Type II pneumococcus were practically never encountered in the buccal secretions; Type III on the contrary was found in 28 per cent. of the cases. Type IV was most frequently encountered, appearing in 53 per cent. of normal saliva. In contrast to these figures the Rockefeller Institute investigators showed that in a series of 454 cases of lobar pneumonia, either pneumococcus Type I or pneumococcus Type II was present

in 62 per cent. of the cases; Type III was present in only 13 per cent.; Type IV in only 20 per cent. of the cases. In other words, the pneumococci most commonly present in the mouth secretions of normal individuals give rise to a minority of cases of lobar pneumonia. A study of the types of pneumococci present during convalescence in pneumonia revealed the fact that only in exceptional instances did one find for a considerable time after recovery the same type of pneumococcus with which the individual was infected during the disease. Usually, the infecting organism was found to have disappeared in three or four weeks after the illness. These observations afforded further evidence that infection in pneumonia occurred from without. Other observations indicated that carriers of virulent pneumococci probably played an important part in the dissemination of the disease. It was also shown that the pneumococcus was more frequently present in the dust of rooms in which pneumonia had occurred than in dust in rooms in which no pneumonia had existed. Moreover, the type of pneumococcus found in the dust corresponded to the type of pneumococcus found in the patient. It was probable that *Streptococcus hemolyticus* pneumonia as it existed in army camps was transmitted from man to man by direct or indirect contact. The mouse method was undoubtedly the quickest and most reliable method of determining the type of organism in pneumonic sputum. In closing, Dr. Cecil again emphasized the importance of accurate bacteriological examination, and said that if Type I pneumococcus was present the administration of Type I serum was to be seriously considered. The time had come when medical men should think of pneumonia in terms of the causative agent rather than in terms of anatomy or pathology.

Serum Treatment and Management of Lobar Pneumonia.—Dr. W. W. HERRICK presented this paper. (See page 948.)

Complications.—Dr. NELLIS B. FOSTER made this contribution. (See page 950.)

Convalescence.—Dr. CHARLES N. B. CAMAC discussed this phase of the subject. He stated that he had had several opportunities during the winter to speak of pneumonia and he had never lost an occasion to speak of Dr. Cecil's work. He thought that Dr. Cecil's monographs were most enlightening. Unlike most monographs, recording detail laboratory technique, every paragraph was readable and could be understood by the general practitioner. Furthermore, Dr. Cecil had summarized his investigations so that they could be applied at the bedside. Coming to his subject, Dr. Camac said he considered convalescence, as related to lobar pneumonia, a rather limited subject because the practitioner felt that when the crisis was passed the patient would rapidly go on to complete recovery. Unlike typhoid fever and some other conditions, the fight was practically over when the crisis of lobar pneumonia occurred. In 1916, he had begun to use the serum at the Gouverneur Hospital and during that winter it had been necessary to send the sputum by runners to the Board of Health laboratories to have the examinations made. That year Dr. Cole had given them the serum prepared at the Rockefeller Hospital Laboratory. Since that time, with the exception of the war, they had used the serum at the hospital systematically. During the war he had also had the opportunity to use it in the military hospitals. That made practically four years' experience with the use of the serum. His feeling was that the convalescence of patients treated with the serum presented an entirely different picture from that presented by patients in whom the serum was not administered. The investigations of the Rockefeller Institute and of the Army Medical School made clear the necessity of using more carefully the term pneumonia. One must first consider clinically whether it was a lobar or a bronchopneumonia or whether it was that new condition we had learned to recognize as pneumonitis, the latter probably a *Streptococcus hemolyticus* infection. Those three groups were recognized pretty generally by the physical signs. Pneumonitis seen in connection with influenza and measles was characterized by a complete infiltration of the lungs and pleura. In these cases the lungs at autopsy might best be described as looking like a sponge dipped in bloody fluid; they were practi-

cally soaked in bloody exudate. These patients drowned in their own exudate. One could tell that the exudate was increasing by the character of the râles, until finally the bloody exudate bubbled out of the nose and mouth and the individual drowned in his own excretions. This condition was seen among the soldiers during the epidemics but it was seldom seen in the civil hospitals. In this condition the mortality was extremely high and the convalescence was protracted and threatened with sequelæ. A second point of importance in connection with the pneumonias was the bacteriology. We had the pneumococcus pneumonias of the various types, the *Streptococcus hemolyticus* and other streptococcus pneumonias and the pneumonias due to other organisms that had been mentioned. In dealing with patients it was necessary to make a distinction and to realize how dangerous it was to allow certain types of pneumonia patients to get away from medical care. Pathological investigations had been made upon individuals who had died with a beginning process in another lobe while they had succumbed to a process elsewhere in the lung. A study of the pathology showed that in pneumococcus pneumonia the involvement was a surface affair. Only the mucous membrane was involved and this was in sharp contrast to the streptococcus (specially hemolyticus) pneumonia. *Pneumococcus mucosus* (Type III.) differed from Type I and II pneumococcus in virulence but not in the histological pathology of the lung. Hence in Types I and II convalescence was more rapid than in pneumonia of the *Streptococcus hemolyticus* variety. The fact that pneumococcus pneumonia was a surface process must not be taken as evidence against its systemic character, for Dr. Cecil stated that the pneumococci invaded the blood stream in from six to twenty-four hours after injection. In the clinical consideration of pneumonia it was a very significant fact that out of 529 cases of pneumonia in the Rockefeller series 454 were of the pneumococcus type; of his own series of 139 cases, Dr. Camac stated that 81 were due to the pneumococcus. We had evidence therefore in lobar pneumonia, accurately observed and studied bacteriologically, that the large majority of cases diagnosed clinically as lobar pneumonia were due to the pneumococcus. Where one had the opportunity to study and determine the bacteriology of pneumonia cases the information was of great importance in determining the rapidity with which they would recover. Dr. Camac recalled that they were very late in studying pneumonia intensively; that most of the medical meetings at which pneumonia was the subject the discussion had centered on digitalis and "How I treat pneumonia." Very little consideration had been given to the etiology of this complex disease until recently, yet according to Osler it was the most fatal of all diseases, outranking diphtheria and tuberculosis. In a series of 46 cases at Gouverneur Hospital 22 were successfully treated with serum and 14 recovered without serum. The deaths were classified in four groups: (a) moribund on admission, or dying at the end of thirty-six hours; (b) dying at the end of seventy-two hours; (c) dying on the fifth day; (d) admitted late with complications. Including all deaths there was a mortality of 23.8 per cent. Excluding all those who died at or before seventy-two hours the mortality was 6.5 per cent. Regarding those treated with serum he would emphasize the fact that during convalescence these patients did not have the toxic appearance of the older cases. In fact within twenty-four hours after the administration of the serum he had seen these patients reading the newspapers and wanting to sit up in bed. Their rule was to retain cases for two weeks after the last dose of serum, if possible, though it was frequently difficult to keep them in the hospital more than eight or ten days. The reason for keeping the patients treated with serum for two weeks was to determine whether any serum sickness would develop, as at times that was deferred as long as two weeks. In regard to the danger of serum sickness, he would deny that it had any danger comparable in any way to the danger from the disease. It should be remembered that in dealing with pneumonia one was dealing with a killing disease so that a mild inconvenience from serum sickness for a few days or even for a few weeks was of minor importance, even though there might be a hematuria.

If the effects of serum treatment occurred outside of the hospital it would be considered that it was something that should have been treated before the patient was discharged from the hospital. A marked contrast between convalescence from pneumococcus pneumonia and from streptococcus bronchopneumonia was the danger in the latter condition by exposure of the patient to cold air. That had been brought home to him forcibly during the epidemics in the army. At the end of one of these epidemics seven convalescent pneumonia patients remained in a large ward, which had been used exclusively for those suffering from this infection. The hospital was crowded and the ward was urgently needed for incoming patients with other maladies. Transfer of the pneumonia convalescents (influenza and measles bronchopneumonia) to another building was determined upon. The patients were wrapped up warmly and taken to another barracks. One of these men immediately redeveloped a bronchopneumonia and died; he had been up about the ward and free from symptoms. Therefore in bronchopneumonia of streptococcus origin warmth and fresh air were important. These cases were extremely sensitive to cold air even late in convalescence. On the contrary, the cases of lobar pneumonia were benefited by open air during convalescence and even during the acute stage. Lobar pneumonia (pneumococcus) cases should be placed on balconies and verandas from 11 A. M. to 4 P. M. The patients should be thoroughly covered, including the head. Screens should be used to prevent currents of cold air. Dr. Camac summarized his remarks as follows: (1) More accurate use of the term pneumonia, clinically and bacteriologically was needed. (2) This accurate knowledge of the pathological process present was necessary for prognosis and treatment, both during the acute stage and convalescence. (3) When serum had been used the patient should be kept under observation for two weeks after the last dose of serum so as to avoid manifestations of serum sickness developing after discharge. If the patient refused to remain this long he should be directed to return for observation should skin manifestations or other symptoms appear. (4) Serum sickness in its most annoying form had not the seriousness of the pneumococcus infection—no fatalities from serum sickness had been reported. (5) Open air was indicated for lobar pneumococcus pneumonia, warmth and indoor fresh air for streptococcus bronchopneumonia.

Dr. WARFIELD T. LONGCOPE said we were very fortunate in hearing these four discussions which had put so clearly and concisely the facts in reference to this common and often fatal disease. There were so many points worthy of discussion that it was impossible to touch upon them all so he would select only a few here and there in the four papers. Dr. Cecil had brought out the relative mortality in the different groups of pneumococcus infection, I, II, III, and IV, together with the mortality in streptococcus pneumonia. He thought we would have to realize always that pneumonia which was really an epidemic disease varied in different years as regards its mortality, not only as to one group but as regards all groups. While the statistics at the Presbyterian Hospital were not completely worked up and could not be used at present there were a few facts that stood out. One was that in certain years, pneumonia was a very fatal disease. In the years 1914 and 1915 pneumonia was a very mild disease and the mortality for any of the groups rarely exceeded 20 per cent., and was as low as five and six per cent. for the serum-treated Type I cases. In 1915 and 1916 the mortality was extremely high for the second and third groups, and even for the fourth group it was 24 per cent.; for Type III pneumonias it was between 50 and 60 per cent.; for the serum-treated Type I pneumonias it was that year only about 10 per cent. So in order therefore to determine the mortality in the different groups we must consider the variability of the disease in the different epidemics. Dr. Longcope said he agreed with everything Dr. Herrick had said. As to the Army cases treated by serum, Dr. Longcope said he was in the Surgeon General's office when those statistics were collected and as they came in he was very much surprised to see how low the mortality in the group I in-

fections was at that time. Of course one must remember that the patients from whom the statistics were gathered were young healthy men. Dr. Foster had spoken of meningitis and the inability to treat meningitis as a complication of pneumonia. Since we did not know much about meningitis as a complication of pneumonia, it was desirable to obtain as much information as possible in reference to it. He had been surprised to find a large proportion of pneumococcus meningitis cases occurring both as a complication and independently of pneumonia due to Type I pneumococcus. That raised the question as to whether one group of pneumococci could invade the meninges oftener and more easily than the other groups. Another complication that Dr. Foster spoke of was lung abscess, not necessarily as a complication of pneumonia, but lung abscess as it existed as a complication of various conditions. Recently we had been seeing a great deal of lung abscess, and from a bacteriological study of the sputum and from material obtained at operation and autopsy it had seemed that it was more common in cases of pneumonia due to the *Streptococcus hemolyticus* than in other varieties of pneumonia. Certainly at the Presbyterian Hospital bacteriological studies seemed to indicate the *Streptococcus hemolyticus* was a frequent cause of lung abscess. Statistics had recently been collected from 44 cases of lung abscess occurring during the last three years at the Presbyterian Hospital. The diagnosis was frequently extremely difficult and the physical signs extraordinarily slight for such extensive disease of the lungs. The actual diagnosis in many cases was really made on the character of the sputum or the x-ray examination, or a combination of the two. The character of the sputum was familiar to all, but there was one point in the x-ray examination of the chest which was of great value in determining whether an abscess was present, namely, the fluid line and the shifting of the fluid line by change of position. Many abscesses were quite localized and in a good x-ray plate when the patient was in the erect position there would appear a semilunar area in the upper portion of the shadow, and when the patient was turned on his side this semilunar area shifted to the upper surface of the shadow. Dr. Camac mentioned serum disease as a complication of cases treated by serum. Occasionally serum sickness occurred and patients might have a relapse. Even if a patient was in the hospital for two weeks, he might have a relapse of serum disease after that time. Only one other point, Dr. Camac spoke of the dangers of serum treatment. In Dr. Longcope's opinion there was no danger of serum disease itself, though there might be some discomfort in having hives. There might, however, be danger in the first administration of serum intravenously. In order to avoid this danger even in such rare cases a method that was quite generally employed was to test the patient's reaction to horse serum to determine whether he was hypersensitive. He had often heard stated that 1 c.c. of horse serum would desensitize a sensitive person but he thought there was no real evidence to uphold that view. As a matter of fact it was extremely difficult to give serum to a person naturally sensitive to it, such as a person who was asthmatic to horse serum. In order to test for sensitiveness he injected 0.02 c.c. of 1-10 or 1-100 dilution of horse serum intradermally, using a saline solution as a control. If no urticarial wheal was produced after one hour, 1 c.c. of horse serum was given subcutaneously and if that did not produce a reaction the serum could be given intravenously. Should the intradermal or subcutaneous test produce a reaction attempts might be made to desensitize the patient by the Besredka method, though this was often unsuccessful.

Dr. RUFUS COLE said he had written so much and talked so much on the subject of pneumonia that he had not much left to add, especially after this extremely interesting discussion which covered almost all the points concerned. One interesting point had come out in his review of the epidemiology of pneumonia in this and other countries. It was generally supposed that there was more lobar pneumonia in America than in England and France, but a closer study of the statistics indicated that pneumonia was about equally prevalent in all countries, and he

imagined that the presence of lobar pneumonia was no greater in this than in other countries. Of course he had been most interested in the serum treatment; that was one of the chief practical points that had come out of their work carried on for a number of years. It was not a very grateful task to criticize the way in which serum was given not only in pneumonia but in other conditions as well. There were a number of therapeutic measures which were life-saving. A physician could be actually responsible for saving but a limited number of lives in the course of his lifetime. Serum even where it was specific, as in diphtheria, was often administered in such a way that he wondered that any good results were obtained. Sir David Bruce had concluded that it was doubtful whether during the war the use of antitetanic serum in the treatment of cases of tetanus had been of any value. It seemed certain, however, that where this serum was correctly and intensively employed it might be of value. To be of value antinephritis serum must also be correctly employed. It was not at all easy to immunize a series of animals without loss of life, and if it was difficult to immunize a normal healthy animal, how much more difficult was it to immunize a sick patient! It could not be done simply by giving a dose three times a day. Theoretically Type I serum should be effective in Type I cases and he had treated a sufficient number of cases to show that it was effective. But unless it could be applied properly it should not be applied at all. There was a large amount of statistical data to show that following the administration of serum, pneumococci disappeared from the blood, and he laid more stress upon this fact than upon mortality statistics in drawing conclusions concerning the value of the serum. If the serum was of value in saving life it should be employed even though the method of its application was complicated. Surgery was complicated and very expensive and yet he had used it.

Dr. HENRY T. CHICKERING stated that in his opinion Dr. Herrick's statement as to the value of rest in pneumonia was of great importance. Most patients were over-treated he thought. Dr. Chickering said that fortunately he had the opportunity to see the results of serum treatment not only in civil practice but also in the army and it seemed to him that the serum treatment was of great value in Type I infections. Of course in the army the mortality from pneumonia was low—in young adults about 10 per cent. It was therefore much more difficult to demonstrate the efficacy in these than in civilian practice where the mortality was greater. At the Rockefeller Institute the mortality had varied slightly from year to year as Dr. Longcope said, but the average was pretty constant in all the groups of pneumonia. The mortality of Type I pneumonia infections treated with serum and reported from other cities paralleled those observed in New York. Consequently a series of 160 treated cases of Type I was a fairly good group to at least get an impression as to the value of serum therapy. In the first place those cases with bacteriemia, unless the bacteriemia was of a severe grade, were cleared up with one dose of anti-pneumococcus serum and the mortality was definitely less in the remainder. In the army, Dr. Chickering said, he had studied a group of Porto Rican laborers among whom there were forty cases of Type I infection in the course of about one month. These men were poorly nourished and suffering from intestinal diseases, parasites, etc., and yet the mortality was only 5 per cent. That group did better than the white soldiers treated in the South, but they were few in number. One should make up one's mind when one first saw a case of pneumonia whether one was going to use serum or not, and if one intended to use serum the sputum should be typed immediately and the serum applied at once. In many cases the physician did not become interested until the patient became very ill. It put a great strain on the effectiveness of the serum when it was employed on the sixth or seventh day of the disease. The use of pituitary was mentioned in one of the papers; he felt, however, that one of the important factors in the treatment of pneumonia was to avoid cathartics. Much distention was avoided by the avoidance of cathartics.

He therefore felt that it was better to depend upon enemata. The cases in which it was necessary to use pituitrin were those in which there was great toxemia. The effect of pituitrin was usually brief and the distention rapidly recurred within a short time after its administration.

Dr. ORRIN G. WIGHTMAN said that the public had become so well versed in laboratory methods that the general practitioner had to be carefully guarded in his statements as to the duration and intensity of an attack of pneumonia. Patients were wont to inquire as to the type and they occasionally ventured a prognosis on their lay knowledge of the disease. Dr. Wightman said he believed in differentiating the type as soon as possible, as it was not only of academic interest but of distinct importance in directing the treatment. However, there was frequently too much time spent in the laboratory and not enough clinical study at the bedside. He strongly advocated giving the patient a chance to fight his own disease with his own resources. The management of a case of pneumonia required good generalship, as the battle was won or lost in twelve days. Formerly our best teachers advocated the free use of alcohol; we were to push it until the tongue became moist. In spite of this most of the cases survived. Oxygen has always been advocated in the cyanotic state in pneumonia but Quimby has well said that a patient could be suffocated by its over use. It was all well enough to administer it and the response was immediate but the withdrawal might leave the patient in collapse. Dr. Herrick had used a timely caution "that oxygen should be properly given." Dr. Camac described in an admirable manner the lung condition found in cases of pneumonitis. The lungs were so acutely congested and the attack had been so intense that they were actually waterlogged—the patients drown in their own secretions. A further study of the autopsies disclosed a number of interesting data. The suprarenal glands frequently had hemorrhages, the blood pressure was invariably low, showing an unmistakable connection. These cases bore cold badly and the old cold air treatment was entirely out of place. They were acute infections of the lung, with loss of suprarenal balance. Again many of them have subsequently returned with evidences of mediastinal gland involvement. This with the lowered resistance produced by defective and diseased suprarenal glands had made it easy for latent tuberculosis to assert itself. We should therefore be on our guard to carefully examine every postpneumonitis lung to see that they were not starting up a tuberculous process. Standardization of the prevailing types of pneumonia was all important, and the laboratories were indispensable. As to the use of digitalis, we must not be carried away by any fad which prescribed either unnecessary dosage or dangerous dosage. The medical profession had handled this drug with satisfaction, each one learning to use the form he liked best. Cases went into collapse from overdose just as well as from underdose. The best type of protection against pneumonia was a rapid resistance on the part of the body in its individual ability to manufacture antibodies. As to serum treatment, this offered a careful study for the future. One fact must not be lost sight of, namely, that any foreign protein introduced into the blood stream would produce an active reaction with its consequent leucocytosis. This leucocytosis was not specific but helpful. We should not confuse these two processes but at the same time we should take advantage of any protective body process until we knew of something better.

Dr. MORRIS MANGES took exception to Dr. Foster's statement as to the harmlessness of repeated tapping of the chest in cases of pneumonia to establish an early diagnosis of empyema. There was far more danger in this procedure than was usually believed. Only ten days ago a young man died suddenly at Mount Sinai Hospital during an exploratory aspiration of the chest to establish such an early diagnosis of empyema. The patient collapsed while the needle was being introduced and all efforts to resuscitate him failed. Dr. Manges knew of a number of similar disasters which had been published, and he referred to a case of his own where an aspiration of a tuber-

culous effusion in the pericardial sac was followed by a permanent hemiplegia. This case was reported the *New York Medical Journal*, Sept. 19, 1908. It was also well to recall the work published some years ago by Capps of Chicago in which experimentally he showed the severe reflex effects from irritation of the inflamed serous membranes, especially the pleura. Even in patients who were acutely ill there was a considerable risk in aspiration of the chest, as was well brought out about ten years ago in the paper published by Hughes Dayton from the New York Hospital. It was only after the clinical signs had been checked up by x-ray examinations (preferably in the sitting posture) that one should attempt diagnostic exploratory aspirations of the chest. Then at least we knew when and where to aspirate.

Dr. FERGUS BUTLER said that in reference to the complications of pneumonia, Dr. Foster had spoken of the surgical complications of empyema and lung abscess; there were also changes associated with the pericardium and occasionally abscess of the mediastinum. All these they had encountered in the empyema service at the Walter Reed Hospital. As the mortality varied from year to year so the incidence of complications varied from year to year, but it was worth considering that every pneumonia was potentially a surgical case. With that thought in view and the high ratio of empyema due to pneumonia in comparison with empyema due to gunshot wounds, the ratio being five of the former to one of the latter, they had in the early months of 1920 regarded every pneumonia case as a potential empyema. In order that the empyemas might be recognized early, the surgeons came into contact with the cases early and followed them through. Then if an empyema developed it came to the surgeon not as an unknown quantity but well known because the surgeon had been following it. Dr. Butler stated that he was speaking not from the standpoint of the internist but from that of the thoracic surgeon realizing the fundamental principles upon which the handling of pericardial effusion and lung abscess was based. Dr. Foster had emphasized that one must carry out the treatment on the basis of a correct diagnosis inasmuch as streptococcus and pneumococcus pneumonia were two different entities requiring different treatment if one was to get good results. At the Walter Reed Hospital they had a chief of the x-ray department, a chief of medicine, and a chief of surgery, and the three men functioned as a group in caring for acute chest conditions. They found that daily bedside x-ray examinations were practically invaluable. The surgeon was the head of the team charged with not merely knowing the clinical course of the disease in each patient but actually demonstrating the surgical complications and instituting the proper treatment.

Dr. CAMAC, in closing the discussion, said that Dr. Longcope had advised the intradermal method of testing the patient's sensitiveness to horse serum. Correct interpretation of the intradermal reaction required practice. He felt that with the varied personnel of a hospital staff the safer method of desensitization was in giving 2 c.c. of antipneumococcus serum subcutaneously; then after two hours 3 c.c., after another two hours 5 c.c., making 10 c.c. in all. They had treated two groups of cases, 139 in one group and 46 in the other, and had had only one case of anaphylaxis. That patient was an asthmatic who showed no signs of hypersensitiveness until he had received 80 c.c. of serum when he became cyanosed, respiration became rapid and the pulse bad. After he had had proper treatment to correct the shock the balance of 20 c.c. was given, and in a few hours the temperature dropped and he went on to uncomplicated recovery. The time for the administration of the serum was within the first thirty-six hours. He could not see why one should not give serum and then make the laboratory test, since this first thirty-six hours was most important. As soon as the clinical diagnosis of lobar consolidation was made the desensitization test should be begun, the serum given, and the laboratory examination carried out as soon as possible, but delay during these critical hours might mean the sacrifice of the strategic moment of attack.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

CONNECTICUT MEDICAL EXAMINING BOARD.

November 9 and 10, 1920.

ANATOMY.

1. Describe circulation of blood in a long bone; manner of entering, course within the bone, manner of exit.
2. Describe the tongue: structure blood and nerve supply.
3. In the origin and insertion of muscles in the human body, is motility sacrificed to power or the reverse? Give illustration.
4. Mention muscles moving arm and divide them into groups.
5. Give origin, branches and distribution of the ophthalmic artery.
6. Give a general description of the lymphatic system.
7. Describe the esophagus and give its relations to adjacent structures.
8. Describe a Fallopian tube.
9. Give relations of lungs and pleuræ to the walls of the chest.
10. Describe the radius.

PHYSIOLOGY.

1. (a) How much bile is secreted in 24 hours? (b) How may the secretion be increased? (c) What part does it play in digestion?
2. Under what conditions may phosphaturia occur? What is its significance.
3. and 4. What are the causes of (a) alkalinity, (b) excessive acidity of the urine?
5. Why is each of the following an important article of diet? (a) lettuce, (b) peas, (c) butter?
6. What is amylase? Where is it found? What is its action?
7. Define intrathoracic pressure. Under normal conditions is it positive or negative?
8. Draw a diagram to illustrate a reflex arc for the spinal cord.
9. What is the origin of the red blood corpuscles?
10. What is the fate of the red blood corpuscles?

MATERIA MEDICA AND THERAPEUTICS.

1. Define *Materia Medica*. What is the official standard and how compiled? Define *Therapeutics*. What relation has the "official standard" to therapeutics?
2. Define tincture, extract, ointment, and illustrate each.
3. (a) What is an alkaloid? (b) Name the alkaloids of *nuxvomica* and of *opium*. (c) Differentiate the therapeutic uses of each and give dosage.
4. Name four drugs used hypodermatically, giving dosage. What surgical and clinical precautions should be observed in the administration of each?
5. Name three cerebral sedatives. Give dose and method of administration of each.
6. Give definition of (a) serum therapy; (b) vaccine therapy; (c) illustrations.
7. What is meant by "opsonins" and what is the "opsonic index"?
8. (a) Give physiological action of *santonin*; (b) indications for its use, method of administration, and dose; (c) dangers incident to use.
9. (a) Discuss the following questions: Should or should not physicians' prescriptions be written in Latin? (b) advantages, (c) disadvantages.
10. Write in Latin an unabbreviated prescription for indigestion. Give metric dosage.

ANSWERS.

ANATOMY.

1. *Blood Supply in a Long Bone*.—"The medullary canal of a long bone is supplied by a large artery (sometimes more than one) called the *nutrient artery*. It enters the bone by the nutrient foramen, which is usually near the center of the shaft, runs in an oblique canal through the compact structure, giving off branches to

this structure, and enters the medullary cavity, and sends branches upward and downward. These branches communicate with branches from the periosteal vessels and subdivide into capillaries, which pass into comparatively large vessels. The walls of the vessels are very thin, and in some places deficient; the venous blood enters the spaces of the red marrow, and the current becomes extremely slow. Small veins collect the venous blood and emerge from the bone. In the humerus the nutrient canal is directed toward the elbow-joint; in the radius and the ulna the nutrient canals are directed toward the elbow-joint; in the femur, the canal is directed toward the hip-joint; and in the tibia and the fibula, the canals are directed toward the ankle-joint. The red marrow of the extremities and the medulla of the entire shaft, and the bone of the shaft, except the circumferential lamellæ, are supplied by the nutrient artery. The circumferential lamellæ, wholly, and the cancellous tissue of the extremities, in part, and the medulla of the shaft to a very small extent are supplied by vessels from the periosteum. The extremities of a bone also receive articular arteries. Veins emerge from the long bones in three places: 1. One or two large veins accompany the nutrient artery. 2. Numerous veins emerge at the articular extremities. 3. Many small veins arise in and emerge from compact substance. The latter two classes do not accompany arteries. The veins in the marrow and in the bone are devoid of valves; but immediately after emerging from the bone they have numerous valves."—(Gray's Anatomy.)

2. **THE TONGUE. Structure.** It is composed of two sets of muscles: (1) *The extrinsic*, consisting of the hyo-glossus, genio-hyo-glossus, palato-glossus, stylo-glossus; and (2) *the intrinsic*, consisting of the superior lingualis, inferior lingualis, transverse lingualis and vertical lingualis. The *septum* is a vertical fibrous partition dividing the tongue into two parts; it extends from the hyoid bone to the tip of the tongue. The tongue is covered with mucous membrane, and on the dorsum the anterior two-thirds is covered with *papillæ*; *circumvallate*, seven to ten in number, situated on each side at the back of the tongue, meeting in a V shaped point in front of the foramen cæcum. The *fungiform* papillæ, situated mainly at the tip of the tongue and on the sides; and the *filiform* papillæ, which are the most numerous. The tongue is attached to the hyoid bone, the epiglottis, the soft palate, the pharynx, and the lower jaw.

It is supplied by the lingual, ascending pharyngeal, and ascending palatine arteries.

The nerves which supply the tongue are: (1) The lingual branch of the inferior maxillary division of the trigeminus (sensation); (2) chorda tympani (taste); (3) lingual branch of the glossopharyngeal (taste and sensation); (4) hypoglossal (motor).

3. **The Mechanics of Muscular Attachments.**—"The points of attachment of most muscles are such as to place these organs at a great mechanical disadvantage. This is very evident in a large part of the muscles of the limbs. Take, for example, a muscle which bends the forearm upon the arm. It is attached to the lower half of the front of the humerus, crosses the elbow-joint, and just below this is attached to the ulna. The loss of power involved here is illustrated in a homely way by comparing the effort required to close a door by pulling it toward one, when it is grasped at a point near the hinges, with that which suffices when it is seized near its free edge, where the knob is usually placed. Manifestly the latter method is vastly easier. If the same plan were adopted in the flexion of the forearm, the muscle would be attached high on the humerus and low on the ulna. But, although this would be advantageous as regards the expenditure of force, it would be strikingly otherwise in directions of quite as much importance. In the first place, the contraction of muscular tissue shortens it to one-half its length and no more, on which account the forearm could be bent upon the arm only about half as far as is normally reached. In the second place, there would be a loss of rapidity of movement of the lower end of the limb about proportionate to the gain of power; for the nearer to the hinge the force is applied, the more rapid will be the movement of the long arm of the lever. Then, the occupation by the muscle of each successive portion of the

great triangular space included by it and the two bones when in flexion would be an intolerable interference with the usefulness of the limb, practically reducing the carrying power of the front of the forearm to nothing. There would also be a loss of a great deal of the important ligamentous work of the muscles by their removal from close contact with the joints during their most pronounced activity. Thus it will be seen that the condition which exists, while extremely costly in the matter of muscular expenditure, is attended with advantages which are more than compensatory."—(Gerrish's Anatomy.)

4. **Muscles Which Act on the Arm.**—"The humerus is drawn forward by the Pectoralis major, anterior fibers of the Deltoid, Coracobrachialis, and by the Biceps when the forearm is flexed; backward, by the Latissimus dorsi, Teres major, posterior fibers of the Deltoid, and by the Triceps when the forearm is extended; it is abducted (elevated) by the Deltoid and Supraspinatus; it is adducted (depressed) by the Subscapularis, Pectoralis major, Latissimus dorsi, and Teres major; it is rotated outward by the Infraspinatus and Teres minor; and it is rotated inward by the Subscapularis, Latissimus dorsi, Teres major, and Pectoralis major."—(Gray's Anatomy.)

5. **The ophthalmic artery** is a branch of the internal carotid artery, and arises at inner side of anterior clinoid process, enters orbit through optic foramen, external and below optic nerve; it then crosses over nerve to inner angle of orbit to divide into two terminal branches, frontal and nasal.

Branches arising outside Optic Nerve:—

Lachrymal: accompanies lachrymal nerve over external rectus to lachrymal gland, gives off malar branches to anastomose with deep temporal and transverse facial.

Central of retina: pierces optic nerve, runs in its substance to retina.

Branches arising over Optic Nerve:

Posterior ciliary: divided into two sets. *Short* (10) perforate sclerotic and supply choroid. *Long* (2) pass forward between choroid and sclerotic, anastomose with anterior ciliary and supply iris and ciliary processes.

Supra-orbital: ascends with frontal nerve over muscles, etc., to supra-orbital foramen; passing out, ascends over frontal bone.

Branches arising internal to Optic Nerve:—

Muscular, superior and inferior: to muscles of orbit, give off anterior ciliary (6-8), which pierce sclerotic behind cornea.

Ethmoidal: anterior and posterior to ethmoidal cells, through anterior and posterior internal orbital canals respectively, supplying also dura mater, the anterior accompanying nasal nerve to skin of nose (anterior nasal branch).

Palpebral (2): one for each lid, arise near pulley, form an arch in each lid, and supply lachrymal apparatus.

Terminal Branches:—

Frontal: turns upwards round inner margin of orbit; anastomoses with supra-orbital.

Nasal: over tendo oculi to root of nose; anastomoses with nasal and angular of facial.—(From *Aids to Anatomy*).

6. "The LYMPHATIC SYSTEM includes the lymphatic vessels and glands and the lacteals, and forms an important accessory to the blood-vascular system, collecting the transuded, unappropriated fluids of the body and the nutritive material derived from the food and conveying it into the venous system. It consists of two main trunks: The thoracic duct, and the right lymphatic duct; and five smaller trunks: The jugular lymphatic trunk, subclavian lymphatic trunk, broncho-mediastinal lymphatic trunk, lumbar lymphatic trunk, intestinal lymphatic trunk.

"Lymphatics have been found in nearly every organ and texture in the body except the brain, the spinal cord, cartilage, tendon, eyeball, placenta, umbilical cord, membranes of the ovum, hair, cutis, and the labyrinth of the ear. They appear to originate as fine capillary nets interwoven among the blood-vessels and proper elements of the tissues, or, more minutely, in the lymph, privascular, and perineural spaces. In the villi they commence as closed, club-like tubes.

"The lymphatic capillaries are somewhat larger than

the vascular capillaries and destitute of valves. Their main trunks pass through lymphatic glands lying in their course, before doing which, however, they divide into afferent vessels, which, on emerging, unite into a smaller number of larger vessels, the efferent.

"In structure, they are composed of three coats—the external fibro-areolar, middle muscular, and internal or endothelial and elastic.

"The *lymphatic glands* are generally situated in the course of the blood-vessels, lymphatic vessels, or lacteal vessels, being accumulated together in certain localities, as the neck, abdomen, axilla, etc. The lymphatic glands and vessels are named from the regions they occupy or the vessels they accompany, and consist usually of a superficial and deep set. Thus, we have cervical, axillary, mediastinal, lumbar, inguinal, etc., and the lymphatic vessels corresponding.

"The *lacteals*, or chyliferous vessels, are the lymphatic vessels of the small intestine, and differ only from the others in carrying chyle during digestion from the intestines to the thoracic duct."—(Young's *Handbook of Anatomy*.)

7. The *esophagus* is a muscular canal, about nine or ten inches long, and extending from the lower border of the pharynx (at the upper border of the cricoid cartilage) to the stomach. It passes down along the front of the spine, through the superior and posterior mediastina, through the esophageal opening in the diaphragm, and ends in the cardiac orifice of the stomach (opposite the tenth dorsal vertebra). It is generally in the median line, but it curves to the left at the root of the neck and again at the esophageal opening in the diaphragm. It is composed of a general fibrous covering on the outside, then a muscular coat consisting of two layers, an outer longitudinal layer and an inner circular layer; inside this is a submucous coat of areolar tissue; and the esophagus is lined by a mucous coat which is covered by stratified squamous epithelium.

Its relations are thus given.—"In the neck:

Anterior.	Left Side
Trachea.	Left interior thy-
Thyroid gland.	roid.
Left recurrent laryngeal nerve.	Left carotid.
	Left subclavian.
	Thoracic duct.
Posterior.	Right Side.
Vertebrae.	Right carotid.
Left longus colli muscle.	Right recurrent laryngeal nerve.

"In the posterior mediastinum: passes forwards and downwards to the left, with the two pneumogastrics, which form a plexus on its surface; the left nerve is anterior, and the right is posterior.

Anterior.	Left Side.
Left carotid artery.	Left subclavian artery.
Bifurcation of trachea.	Left pneumogastric nerve.
Right pulmonary artery.	Arch of aorta.
Left bronchus.	Thoracic aorta.
Left recurrent laryngeal nerve.	Left pleura.
Pericardium and left auricle.	Right Side
Diaphragm.	Right pleura.
	Vena azygos major.
Posterior.	
Longus colli.	
Vertebrae.	
Thoracic duct.	
Vena azygos minores.	
Right intercostal vessels.	
Aorta (below).	

(From *Aids to Anatomy*.)

8. The Fallopian tubes are two in number, placed in the upper margin of the broad ligament. Each tube measures about 4 inches in length. The cavity commences by a narrow orifice called the *ostium internum*, and terminates in a *fimbriated extremity*, which passes over the superior and posterior borders of the ovary, and is attached by the fimbria ovarica to the superior pole of the ovary.—(*Aids to Anatomy*.)

9. "The *lines of reflection of the pleura* from the chest-wall are of considerable importance. *Anteriorly*, on the right side, the line begins opposite the interval between the two heads of the sterno-mastoid, runs down and inwards behind the sterno-clavicular articulation, to meet its fellow at the manubrio-gladiolar junction, generally a little to the left of the middle line, whence it descends almost vertically to the sixth intercostal

space, and then curves outwards, becoming continuous with the costo-diaphragmatic reflection. On the left side it behaves similarly, save that at the level of the fourth costal cartilage it deviates outwards behind the inner extremities of the fifth and sixth intercostal spaces, which thus are in contact for a short distance with the pericardium. *Below*, starting from the sternal end of the sixth intercostal space, the reflection on the right side runs down and outwards, crosses the junction of the seventh rib and its cartilage, crosses the seventh space in the mammary line, and so runs down to the tenth rib behind the midaxillary line. Then it runs inwards to the vertebral end of the twelfth rib. On the left side this reflection commences behind the sixth costal cartilage, but otherwise resembles the right. Generally speaking, a line from the lower end of the gladiolus over the cartilage of the ribs to the lower border of the last rib indicates this reflection with sufficient accuracy. *Posteriorly*, the pleura extend to the costo-vertebral junctions. The *lowest part* of the pleural sac is posterior, behind the twelfth rib.

"The *apex of the lung* projects into the root of the neck, corresponding posteriorly to the spine of the seventh cervical vertebra, and anteriorly to a point nearly 1 inch above the inner end of the clavicle. The lines of the anterior borders correspond to those of the pleural reflections already given. The anterior border of the left lung presents a notch or *incisura* corresponding to the cardiac apex, which is thereby left uncovered by lung. The *BASES*, however, do not reach as low as the pleura. Thus, on the right side the base of the lung extends from the sixth intercostal space in front to the lower border of the eighth rib in the axillary line, and that of the tenth rib in the scapular line, and then runs horizontally inwards to the vertebral extremity of the eleventh rib, the lowest level reached being the ninth intercostal space in front of the scapular line. The lower border of the left lung is similar, but rather lower."—(Macewen's *Surgical Anatomy*.)

10. "The *RADIUS* is a long bone, shorter than the ulna, situated on the outer side of the forearm, the upper end small, the shaft slightly curved, and the lower end expanded to form part of the wrist joint. It consists of shaft, upper and lower extremity. The *shaft* is prismatic, slightly curved, and presents: *An internal border*, sharp and prominent, for interosseous membrane; *An anterior border*, marked at its upper third by an *oblique line*, for attachment of flexor longus pollicis, supinator brevis, and flexor sublimis digitorum; *anterior surface*, affords attachment above for flexor longus pollicis, below for pronator quadratus, and presents at the junction of middle and upper two-thirds a *nutrient foramen* directed upward; *posterior surface* gives attachment at upper third to supinator brevis, and at middle third to extensors of thumb.

"The *upper extremity* presents: *Head*—a cup-like cylindrical cavity, for articulation with capitellum of humerus, and on its side an articulating surface for lesser sigmoid cavity of ulna and orbicular ligament, which nearly surrounds it; *neck*, the constricted portion below the head; *bicipital tuberosity*, below and to inner side, divided by a vertical line into a rough surface posteriorly, for attachment of biceps tendon, and smooth surface anteriorly for bursa.

"The *lower extremity*, large, expanded, and quadrilateral, presents: *Carpal articular surface*, smooth, concave, triangular depression divided by an antero-posterior ridge into an outer facet for scaphoid bone and inner for semilunar; *sigmoid cavity*, a shallow concavity at inner side of carpal end, for articulation with ulnar head; *styloid process*, projects obliquely downward from the external surface, for attachment by its apex to external lateral ligament of wrist-joint, and by its base to insertion of supinator longus muscle. Its outer surface is marked by two *grooves* for extensors of thumb. The *posterior surface* of the lower extremity is also marked by three *grooves* from without inward for the following: Ext. carpi radialis longior and brevior in first, ext. secundi internodii in second, and ext. indicis, ext. communis digitorum, and ext. minimi digiti in third. This surface has also attachment of posterior ligament of wrist."—(Young's *Anatomy*.)

PHYSIOLOGY

1. The amount of bile secreted in 24 hours is about

500 to 1000 c.c. The amount may be increased by the administration of bile salts, of secretin, of salicylic acid, or of ox-gall. There was formerly a long list of so-called choliagogues (podophyllin, aloes, rhubarb, jalap, colchicum, etc.) but their effect on the amount of bile secreted is problematical.

The function of bile in digestion.—It aids the pancreatic ferments in their action on proteins, carbohydrates, and fats.

2. **Phosphaturia may occur** under the following conditions:—rickets, osteomalacia, cystitis, gout, anemia, leukemia and various nervous disorders. Its significance may be slight; frequently it denotes a reduced acidity of the urine.

3. and 4. **URINE.**—"The acidity is more intense than normal in concentrated urines, in fevers, gout, acute articular rheumatism, leukemia, scurvy, and sometimes in diabetes. The acidity of diabetic urine frequently increases after it is voided, with separation of crystals of uric acid, from the formation of acids by fermentation. The reaction may become alkaline from the presence of fixed alkalies, carbonates, or alkaline phosphates, or of volatile alkali, ammonium carbonate. Physiological subacidity or alkalinity is always due to the former, which are also the cause of the alkalinity occurring in anemia, after cold baths, after absorption of alkaline transudates, and after administration of organic acids or mineral alkalies. Alkalinity from volatile alkali always results from decomposition of urea, which takes place in the bladder in cystitis."—(Witthaus' *Manual of Chemistry*.)

5. **Lettuce** has little or no nutritive value; it adds variety and flavor to a meal; and it is usually taken with oil, which is nourishing; its main constituent is water; its bulk may be of value.

Peas owe their nutritive value to the large amount of nitrogen which they contain; they also contain much carbohydrate; they may, to some extent, replace meat.

Butter owes its nutritive value to the large amount of fat which it contains; it is also easily digested and absorbed.

6. **Amylase** is an enzyme found in the pancreatic secretion; it converts starch to maltose and achrondextrin in an alkaline medium.

7. **Intrathoracic pressure** is the pressure which normally prevails in the pleural cavity and mediastinal spaces; under normal conditions it is always negative.

8. **Reflex actions** are involuntary or unconscious movements due to suitable stimuli. They depend upon the integrity of the reflex arc, which is a complex made up of: (1) A surface capable of receiving an impression; (2) an afferent nerve; (3) a nerve cell capable of receiving and also of sending out impulses; (4) an efferent nerve, and (5) a surface capable of responding in some way to the impulse conveyed by the efferent nerve. **Example:** The patellar reflex consists of a contraction of the extensor muscles of the leg and a movement of the foot forward when the ligamentum patellæ is struck; the quadriceps extensor must first be slightly stretched by putting one knee over the other. Its integrity depends upon a healthy condition of the entire reflex arc, consisting of tendon, afferent or sensory nerve, posterior roots, and anterior horn of the spinal cord, the efferent or motor nerve, and the muscle itself.

9. **The origin of the red blood corpuscles** is, for the adult, the red marrow of bones; in the embryo, the liver and spleen may also give origin to these red corpuscles.

10. **The fate of the red blood corpuscles** is to be broken up in the liver; some are perhaps destroyed in the blood stream; the spleen and lymphatic glands have also been mentioned as possible places for the destruction of the red blood corpuscles.

MATERIA MEDICA AND THERAPEUTICS.

1. **Materia Medica** is the name given to the agents used in the treatment of disease.

The Official Standard is the United States Pharmacopœia. This pharmacopœia is controlled by the National Convention for Revising the Pharmacopœia, which meets every ten years at Washington, D. C. The Convention is made up of delegates from the various colleges of medicine and pharmacy, and State and national societies, and from the Army, Navy, and Marine Hospital Service. This work standardizes certain drugs

and preparations, and for this reason should be upheld by physicians; but it has no legal authority, and a physician can use or prescribe anything which, in his judgment, will benefit his patient.

Therapeutics is the science of healing, or the use of any remedial agents.

2. **Tinctures** are alcoholic solutions of medicinal substances (usually non-volatile). Example: Tincture of aconite.

Extracts are solid or semi-solid preparations obtained by the evaporation of solutions of vegetable principles. Example: Extract of nux vomica.

Ointment is a soft, fatty mixture of medicinal agents with a basis of petrolatum or lard; or of fixed oils with a solid fat. They are for application to the skin. Example: Unguentum hydrargyri.

3. **Alkaloids** are, as a rule, solid bodies; contain carbon, hydrogen, nitrogen, and oxygen; have very complex constitution; react with acids to form salts in the same way that ammonia does; are of vegetable origin, as a rule; are extremely poisonous; are optically active, generally levorotatory.

The alkaloids of nux vomica are: Strychnine and brucine.

Brucine is hardly used; it is said to have similar effects to strychnine, but to be less powerful and of slower action. Dose of strychnine, gr. 1/40.

The alkaloids of opium are: Morphine, codeine, thebaine, narcotine, narceine, papaverine, and about a dozen more which are hardly used.

The following "differences" are from Sollmann's *Manual of Pharmacology*:

Morphine.—Produces the strongest narcotic, analgesic, hypnotic, and intestinal effects, and the weakest stimulation. It causes the greatest derangement of digestion; and, with heroine, is most apt to induce a habit. Dose, gr. 1/8.

Codeine is less narcotic, less constipating, and less apt to induce a habit or tolerance. It has some advantage in the treatment of cough. Bastedo uses 15 to 30 mg., but Fraenkel claims that at least 40 to 60 mg. are required to affect cough. This dosage is somewhat quieting, but not narcotic, and scarcely analgesic. Larger dosage produces restlessness instead of quieting. The susceptibility is the same for all ages. It increases the spinal reflexes more than morphine. Dose, gr. 1/2.

Dionine seems to stand intermediate between morphine and codeine in all respects. Mering advises it in cough. It sometimes causes itching of the skin. It has a special action on the conjunctiva (edema). Dose, gr. 1/4.

Heroine approaches still more to morphine, of which it shares all the disadvantages, and over which it has no serious advantage. Dose, gr. 1/12.

Thebaine is so markedly convulsant that it may be placed in the strychnine group.

Papaverine.—This was recommended as an analgesic, but its central effects are insignificant. Its toxicity is low. It relaxes the tonus of all smooth muscle, especially when this has been spasmodically contracted, and this without paralyzing the contractility of the muscle; it lowers blood pressure mainly by peripheral vasodilator action, especially in the splanchnic area.

Therapeutic Use of Papaverine.—It has been advised in gastric and intestinal spasms and colics, and in spastic constipation (30 to 80 mg. by mouth or hypodermic). It is a local anesthetic, and has been used on the cornea as solution of 4 to 10 per cent.

Narcotine.—The peripheral actions appear to be similar to papaverine, but weaker; it is quite toxic to the heart, respiration, and other functions.

Narceine.—The peripheral actions resemble narcotine.

4. **Four drugs used hypodermatically:** (1) *Apomorphine hydrochloride*, dose 1/10 grain, as an emetic; (2) *morphine sulphate*, dose 1/2 to 1/4 grain, according to need, to allay pain; (3) *cocaine hydrochloride*, dose 1/6 grain, as a local anesthetic; (4) *mercury bichloride*, dose 1/48 grain, in syphilis.

"To give a hypodermatic injection the dose is placed in the hypodermic syringe (many liquids cannot readily be drawn up through the syringe needle), the sterilized needle (it may be sterilized in a test-tube or spoon) is screwed on, and the syringe is turned needle upward so that any bubbles of air may be driven out by pressure on the piston. There are two methods of injection

for systemic effect, the *subcutaneous* and the *intramuscular*. In the *subcutaneous method* the properly cleansed skin, usually of an arm or a leg, is pinched up between the thumb and finger of one hand, while the needle is quickly plunged in a slanting direction through the skin into the subcutaneous tissue. In the *intramuscular method* the needle is plunged straight through the skin and subcutaneous tissue into the underlying muscle, usually in the back, buttocks, or chest, though sometimes in the limbs. This method favors ready absorption. By either method, a sharp needle and quick puncture give almost no pain. The fluid is slowly injected, the needle is quickly withdrawn, the point of the puncture is covered to prevent the fluid from running out, and the spot is gently massaged to promote diffusion of the liquid into the tissues. The hypodermatic needle may be cleansed by first forcing water through it and then allowing a few drops of alcohol to descend through it by capillarity. A fine wire drawn through the lumen keeps it permeable. (In the introduction of cocaine and similar drugs for local anesthesia, where a local action only is desired, the needle is inserted just beneath the epidermis and gives a *superficial subcutaneous injection*, or an *intracutaneous injection*. This method is not used when a systemic effect is desired.) (Bastedo's *Materia Medica*, etc.)

5. *Three cerebral sedatives:* (1) *Chloral hydrate*, dose, 15 or 20 grains in solution; (2) *hyosine hydrobromide*, dose, 1/120 grain, either by mouth or hypodermatically; (3) *potassium bromide*, dose, 15 grains, well diluted.

6. "A *serum* is a product obtained by injecting into an animal, usually the horse, a culture (e.g. Diphtheria) or the toxin from a culture (e.g. Streptococcus) of the organism. Serums may be subdivided into—(a) *Antitoxic serums*, such as Diphtheria and Tetanus, which are obtained by injecting filtered cultures into the animal used to provide the serum. (b) *Anti-bacterial serums*, such as Anti-Streptococcus and Anti-Gonococcus, in the preparation of which unfiltered cultures are used. Serums are usually injected in the flank or between the shoulder blades, the skin having previously been cleansed and the syringe carefully sterilized. Cases are on record where they have been given intravenously with normal saline solution and also per rectum.

"A *vaccine* is a finely divided suspension of killed cultures of a microorganism which is injected directly into the human subject. The object is to stimulate the individual to elaborate his own antibodies, which results in increased resistance to the ravages of bacterial infection. Vaccines are of two kinds—(a) *Autogenous*—prepared from the organism isolated from pathological material taken from the patient. (b) *Stock prepared* from virulent cultures of the organism, isolated from other cases of similar bacterial origin. Vaccines are administered by subcutaneous injection by means of an all-glass hypodermic syringe. The site of injection may be the flank, thigh, shoulder, or back. The skin is first sterilized by a pledget of cotton wool saturated with a suitable antiseptic, e.g. lysol.

"Briefly, the difference is that with a serum the opposing influence to the toxins is produced outside the human body, while with the vaccine it is produced inside and the degree of immunity conferred is greater with the latter than the former. It should also be noted that the dose of a serum is much higher, from the standpoint of the amount of fluid injected, than in the case of a vaccine. With the former the dose usually ranges from 10 c.c. to 50 c.c., while with the latter it is, as a rule, not more than 1 c.c." (Holland's *Pharmacy Handbook*.)

Illustration of serum-therapy: The use of antitoxin in cases of diphtheria or tetanus.

Illustration of vaccine-therapy: The use of vaccines in cases of acne or boils.

7. *Opsonin* is that quality of a serum which makes a microorganism more susceptible to phagocytosis.

Opsonic index is the relative amount of opsonins in a serum as compared with the normal standard. It is obtained by dividing the average number of bacteria taken up by a leucocyte under the influence of a given serum by the average number taken up by a leucocyte under the influence of standard normal serum.

8. *Santonin* is anthelmintic to the round-worm. It

is taken into the blood as sodium santoninate, and affects the cerebral faculties and the vision; objects appearing at first blue, green, or red, then yellow, often succeeded by blindness for a week or more. Toxic doses disturb the consciousness of the patient, produce a sort of intoxication, tremors, weakness, with enfeebled respiration and slowing of the pulse, coldness of the surface, vomiting, sweating, mydriasis, convulsions, and death from failure of respiration. The dose is one grain for an adult, not to be repeated soon, as the action of the drug is slow; it is best administered in powder with calomel at bedtime after a day of fasting, a senna-draught or dose of castor oil being used the following morning. (From Potter's *Therapeutics, Materia Medica*, etc.)

9. Formerly, when physicians and druggists knew Latin, it was customary to write prescriptions in Latin. Now, when the study of the classics is being more and more neglected, it is more customary to write them in English. Unfortunately, many physicians write them in bad Latin, and add to the disgraceful jargon by trying to hide their ignorance in abbreviations which frequently increase the possibility of mistakes. The question is largely one of custom. But it should always be remembered that it is more scholarly to write good English than bad Latin; and also that abbreviations are, as a rule, a pitfall, the prescriber may mean one thing and the pharmacist may understand another thing.

Advantages of writing prescriptions in Latin: Latin is supposed to be read by so-called educated people all over the world; hence it is a universal language. Being a dead language, it is not liable to change. It is never ambiguous, but is always clear and explicit. Sometimes it may be advisable that the patient should not know what he is taking.

The only *disadvantage* is to be found in the inability of the physician to write the prescription in Latin, or in the inability of the pharmacist to read the Latin.

10. For indigestion:

R. Extracti nucis vomicæ... 0.25 gm.

Extracti quassie..... 1.80 gm.

Quinina sulphatis..... 2.60 gm.

Misce et divide in pilulas numero xx.

Signa.—One three times a day after meals.

Miscellany.

NEW BOOKS AND OLD.

VII.—THE OSLER LIBRARY AT MCGILL.

BY JOHN RUHRÄH, M.D.,

BALTIMORE, MD.

FOR many years Sir William Osler devoted a great deal of time and energy to making a collection of medical books which will have a resting place at McGill University in Montreal. The library is a very remarkable one, perhaps the finest of the kind extant. There are over 7,800 volumes, many of which, however, contain a number of separate works, so that the card index numbers over 8,250. During the later years of Sir William's life he devoted much time to making a catalogue, but unfortunately did not live to see its completion. The collection is still at Oxford, where an assistant from the Bodleian Library is still working on the catalogue, which will probably be finished by the end of the present year.

In addition to the listing of books there is an introduction and a memorandum on how to use the library. It is expected that some time next year the entire collection will be moved to McGill together with the ashes of the late Sir William.

The Library is divided into these groups of works:

I. Manuscripts.

II. Incunabula.

III. *Bibliotheca Prima*. Sir William's idea was to have in a comparatively small number of works the essential literature grouped about the men of the first rank arranged in chronological order. They illustrate the beginnings of medicine (Lucretius, Anthropology, Primitive Medicine; Medicine in Babylonia, Egypt, Persia, China, India, etc.). The Greeks, the Pre-Socratics. Then the work of the great Discoverers in Medicine up to the nineteenth century, as: Plato, Hippocrates, Aristotle, Theophrastus, Celsus, Plinius, Galen, the Byzantines and Arabians; medieval (Roger Bacon and Leonardo da Vinci); the sixteenth century (Copernicus, Paracelsus, etc.); the seventeenth century (Boerhaave, Boyle, Malpighi, Newton, Sydenham, etc.); eighteenth century (Hunter, Jenner, Dalton, etc.); the nineteenth century (Claude, Bernard, Davy, Helmholtz, Koch, Pasteur, Virchow, etc.). And lastly, the special Harvey Collection of works.

IV. *Bibliotheca Secunda*. Books grouped into alphabetical sections, such as those referring to Anatomy, Antiseptics, Blood-letting, Christian Science, Dental Surgery, Epidemics, Famine, Gout, Inoculation, Midwifery, Ophthalmology, Plague, Surgery, Tuberculosis, Vivisection; altogether some ninety subjects.

V. *Bibliotheca Literaria*. Comprising Literary works by medical writers and Medicine and Doctors in fiction.

VI. *Bibliotheca Biographica*. Medical Biography, arranged alphabetically under the subject of the biographer.

VII. *Bibliotheca Bibliographica*. Medical and General Bibliography.

VIII. *Bibliotheca Historica*. The History of Medicine and Medical Institutions.

An additional interest of many of these books, apart from their rarity and intrinsic worth, lies in the fact that so many of them are annotated by Sir William in his own handwriting.

The temporary committee, appointed by the McGill Faculty of Medicine, consists of the Principal (Sir Arthur Currie, Chairman), the Dean of the Faculty of Medicine (Dr. H. S. Birkett), and a Professor of Medicine (Dr. Finley)—all three of whom, as you will see from the "Memoranda," are to be Curators of the Library upon arrival.

The terms of the will as drawn up by Sir William Osler, on March 24, 1919, as they refer to the Library, are given below:

I. Curators: (a) The dean of the Medical Faculty (chairman), ex officio. (b) the principal of the university. (c) A member of the Osler family selected by the other trustees. (d) The professor of medicine. (e) The chairman of the library committee of the College of Physicians, Philadelphia. (f) The chairman of the library committee of the Medical and Chirurgical Faculty of the State of Maryland. (g) The librarian of the Surgeon-General's Library. The traveling expenses of the trustees from a distance to be paid from the fund. Except for special purposes it should not be necessary to hold more than two meetings a year. Three members to constitute a quorum.

II. The library to serve, as far as possible, two functions: the education of students in the history and methods of science and of medicine, and to promote research into these subjects.

III. The Librarian. (a) He shall be selected by the curators and appointed by the governors of the university. (b) He shall be a member of the Medical Faculty and ex officio professor of the history of science (and of medicine), either of which titles he may use. (c) He shall have: (i) Full charge of the collection, and (ii) appoint assistants; (iii) purchase books; (iv) direct the reading of ordinary students and help special students with researches; (v) lecture when he feels it will be useful, but there should be no compulsion to give set courses. Private advice and instruction in the library should be his chief work. (d) The librarian should be a scholar who has given evidence of interest in Bibliography and the History of Science.

IV. As I wish the position to be a comfortable berth for a good scholar, the salary should at first be not less than three-fourths ($\frac{3}{4}$) of the total income. Later, as the income increases, it should be one-half ($\frac{1}{2}$).

V. As I do not wish to embarrass the university in any way, the income shall at first be used: (i) To pay expenses of transport of the books, arranging space, book cases, etc., and (ii) To help pay for the printing (and preparation) of a catalogue, if that has not been already done before my death.

VI. The librarian shall submit an annual statement to the trustees and the university.

VII. Books are not to be lent or removed from the library.

VIII. The library will: (a) Relieve the university and departmental libraries by purchasing the journals on the history of science and of medicine and the special books and monographs in these subjects, and (b) the librarian will fill all gaps in the works of men of the first order in the various sections.

IX. The library is for the use of the members of the medical profession, including, of course, medical students, and I particularly wish my colleagues of Laval and my French Canadian brothers to take advantage of the many important works of the old masters of their native land, in the collection of which I have had them specially in mind.

X. Special students, from outside Montreal, are to be given every possible facility in the library. (A memorandum on how to use the library will be found at the end of the introduction to the catalogue.)

XI. Knowing how with time conditions change, the curators are at liberty to make alterations in these regulations respecting, as far as possible, my wishes as herein expressed.

A PSYCHOLOGICAL STUDY OF SOME MENTAL DEFECTS IN THE NORMAL DULL ADOLESCENT.*

By L. PIERCE CLARK, M.D.

NEW YORK.

For several years by means of careful mental tests we have steadily detected a large group of individuals in schools and industrial life who have shown an intelligence beyond that found in the more marked cases of mental arrest. Practically no one, however, has made an attempt to determine and classify the exact degree of qualitative mental disorder from which these individuals suffer. Out of these types of intelligence defects are recruited many socially unstable, delinquent, and aberrant types of transient psychoses. It is highly important that we should make an effort to understand the psychology of the emotional life of the so-called normal dull person and determine to what extent the state is remediable or adaptable to the end of good mental health. While a considerable portion of this contribution is devoted to outlining, from a psychological standpoint, the quantitative detection of the normal dull person, a matter of more importance is to direct specific attention to the qualitative aspects of the minds of such individuals.

Many laymen and not a few physicians have hoped that certain types of mild states of feeble-mindedness might be removed or outgrown. Some endocrinologists continue to hope for this outcome in psychasthenics. They hope for this, in part at least, by viewing the results which have been obtained from thyroid feedings in cretinism and allied states. While there are still chances for a wider and more exact extension of endocrinology in mental defects, as yet it has not materially altered the general statement that once a definite determination of any degree of feeble-mindedness has been made in a child, the condition which remains is hopeless so far as recovery or cure is concerned. Many of us, still optimistic, have searched for that slightest grade or border-line of mental retardation which, by intensive and careful treatment, plus specific medical therapy, may be overcome.

The type of mental retardation which most nearly comes within this optimistic viewpoint is that now classified as the normal dull person. But probably our old therapeutic hope to cure or remove even this slight defect will meet with as

*Read before the Section of Neurology and Psychiatry, N. Y. Academy of Medicine, December 14, 1920.

great a disappointment as in the training treatment of the pronouncedly feeble-minded. For even in the normal dull person the successful outcome in handling such mental defect is by the old, well-proven procedure of education and better adaptation of the individual to his life purposes at the level of his innate capacity.

The fault in many normal dull persons is not simple deficiency of intellectual power. Indeed, the detection of this fault is a relatively simple task compared with an analysis of the psychopathic traits. Just what part mental retardation plays in inducing or encouraging conduct disorders in the so-called normal dull person is a nice question. In all probability the mental defect plays a much less significant role than the average layman or even teacher has inferred. No doubt an inability to keep pace in the average normal school class encourages the dull scholar in no small degree to seek vicarious and abnormal outlets of interest and preoccupations, but is this delinquent tendency resisted in those otherwise properly endowed mentally? For instance, being reduced a grade or repeating a grade is by no means uncommon in school experiences. A fair estimate of its benignity is given me by Miss Farrell, Superintendent of the Ungraded Class System in New York, who states that it occurs in about 1 per cent. of the pupils in all classes. We would, therefore, rightly infer that there is a qualitative as well as a quantitative defect in the character, analogous to that seen in some feeble-minded in whom there is a subinhibition of the instincts shown in different forms of delinquency. Nor can one postulate the ratio of defect in the emotional and social instincts as compared with the quantitative defects of the mental faculties classified as more strictly intellectual. At best one may say that the keener the dull person is aware of his intellectual defect, plus a desire to find some way out, entails not a little strain upon the proper control of character weakness. However, inasmuch as the greatest intellectual faults in case studies are frequently encountered when this moral and spiritual conflict has been seemingly little evidenced, one may easily over-emphasize such a rationalization of cause and effect. Perhaps one had best not attempt any such hypothesis in face of the fewness of data and the inaccurate analyses made in both fields of study (*i.e.* in quantitative and qualitative defects of mentation of the normal dull person). At present it would seem as in the normal person that character, as we commonly speak of it, is quite distinct from the type of intellectual equipment. Exact data in this field are perhaps of

more practical value than one at first sight might suppose. At present effort at relief is largely devoted to improving the intellectual standing of the normal dull person. Only comparatively recently have we begun to realize that character and conduct training is something quite apart from the purely scholastic curriculum of instruction. While no doubt the pedagogic pacing in the normal dull person needs to be slower, more detailed, and repetitive, the essential striving for proper habit and conduct training needs to be somewhat the same in the qualitative sphere of the mind. A mistake is often made in the lack of personal enthusiasm and color in the work laid out. Abstract studies and unstable occupations, such as salesmanship, etc., are not to be encouraged. A concrete education along industrial lines is of greatest value. Practically no institutions exist that provide the proper community environment and ethical training, combined with the amount of restriction, which the normal dull student needs.

We will give our attention for a short period to a review of what has been undertaken by the psychologists in testing out this recently classified group.

However uncomplimentary it may seem to the neuropsychiatrist, we must admit that the more exact recognition of the slighter grades of mental defect was first brought out by the psychologists through their carefully considered tests. However, from the nature of their work with the feeble-minded we might have expected this to be the case. While we have all known of the borderline cases, yet it was thought that even these, on more precise analysis, might be classified either as quite normal or mentally defective. The psychologists, and especially Terman, have divided these into two groups, using the term "borderline" to designate those who are very near the upper limits of feeble-mindedness, and the term "dull normal" for those who more nearly approach average-normal intelligence. Such terms as "backward," "dull," and "retarded" are sometimes used to describe this near-normal group.

Persons of dull-normal intelligence are not feeble-minded, nor do they often fall near enough that group to be considered borderline cases. Yet they are seriously enough retarded to make it necessary that they be differentiated from those who are fully equal to average persons of the same age. To what extent this mental retardation may be due to external factors, such as physical defects, malnutrition, poor training, etc., and how much be due to actual inferiority in natural mental equipment, are problems which clinical psychologists are attempting to solve.

One hundred and fifty-one successive entrants at the San Quentin Prison were tested by the Stanford Revision of the Binet-Simon Intelligence Scale and by three other series of standardized tests.* All degrees of intelligence were found between seven and one-half years mentality and that of very superior adults. Of the total number, 39, or 25.2 per cent., were classified as dull-

normal. It appears that individuals of extreme mental inferiority are directly responsible for at least one-fourth, and possibly for one-third of the total amount of delinquency and crime. But, on the other hand, so far as the prison records go, there is a somewhat smaller proportion of repeaters among the feeble-minded and borderline cases than among those of higher intelligence, which include the normal-dull cases.

When we use such terms as feeble-mindedness, borderline intelligence, dullness, normality, superior intelligence, and genius, Terman* suggests that two facts be borne in mind: (1) That the boundary lines between such groups are absolutely arbitrary, a matter of definition only. (2) That the individuals comprising one of the groups do not make up a homogeneous type. Nevertheless, since terms like the above are convenient and will probably continue to be used, it is desirable to give them as much definiteness as possible. On the basis of tests that have been made, including many cases of all grades of intelligence, Terman offers the following suggestions for the classification of intelligence quotients:

Intelligence Quotient	Classification
Above 140	"Near" genius or genius.
120-140	Very superior intelligence.
110-120	Superior intelligence.
90-110	Normal, or average intelligence.
80-90	Dullness, rarely classifiable as feeble-mindedness.
70-80	Borderline deficiency, sometimes classifiable as dullness, often as feeble-mindedness.
Below 70	Definite feeble-mindedness.

In the dull-normal group (intelligence quotient 80 to 90) are included those children who would not, according to any of the commonly accepted social standards, be considered feeble-minded, but who are, nevertheless, far enough below the actual average of intelligence among races of western European descent that they cannot make ordinary school progress or master other intellectual difficulties to which average children are equal. A few of this class test as low as 75 to 80; but the majority are not far from 85. Those testing 80 and 90 will usually be able to reach the eighth grade, but ordinarily only after from three to four failures. They are very numerous.

The following are typical examples of school children belonging to this class:†

Boy, tested at the age of 10-2; intelligence quotient, 83; and again at 14-1; intelligence quotient, 79. His mental age in the first test was 8-6, and in the second test 11. He was the son of a barber, who was dead. The mother was capable, and made a good home for her children. At 10 years this boy was doing unsatisfactory work in the fourth grade, and at 12 unsatisfactory work in low sixth. He was good looking, normal in appearance and social development, and though occasionally obstinate, was usually steady. Any one unacquainted with his poor school work and low intelligence quotient would consider him normal, and he possessed no physical or moral handicaps that could pos-

*L. M. Terman: "The Measurement of Intelligence. An Explanation and Complete Guide for the Use of the Standard Revision and Extension of the Binet-Simon Intelligence Scale," 1916.

†Terman: "The Intelligence of School Children," 1919.

*L. M. Terman, J. H. Williams, Grace M. Fernald: "Surveys in Mental Deviation in Prisons, Public Schools and Orphanages," Cal. State Joint Com. on Defectives, 1918.

sibly account for his retardation. He was simply dull, and was able to meet a purely vocational training.

Girl, aged 12-4, whose mental age was 10-1; intelligence quotient 82. She had an average home environment, with excellent educational advantages. At 12 years she was doing very poor work in the 5th grade. Her appearance, type of play and attitude toward other children were normal. She was simply dull. She was not likely to make the high school.

Many have called attention to the fact that normal dull persons are not necessarily undesirable members of society. Indeed, the world has abundant use for them. A large proportion of the tasks of modern society can be as well, or better, performed by individuals belonging to this class as by those of superior intelligence. Terman mentions the case of a normal-dull man with an intelligence quotient of 80, who had served several years as policeman in an eastern State at \$65 to \$80 a month. A successful street-car conductor, with an intelligence quotient of 83, was very popular with his patrons because of his genial good nature and his interest in people.

Waugh tested 82 street car motormen and conductors whose work rates as semi-skilled. The investigation showed that an intelligence quotient of 80 to 90 (normal-dull) is entirely satisfactory for this kind of work provided other traits are satisfactory. On the other hand, the data suggested that intelligence above 90 adds nothing to the efficiency of a motorman or conductor and conduces to discontent. Men of normal-dull intelligence usually seem contented and proud of their jobs and find more satisfaction in the performance of their work than individuals of superior intelligence. Though below the average in mental endowment they are not necessarily defective since they are able to manage themselves and their affairs with reasonable prudence, can do semi-skilled and sometimes even skilled labor. Thus the normal-dull person is to be considered a potential social asset of great value. To make the most of him, however, he must be trained, otherwise he may fail and drift into the ranks of the antisocial.

From an analysis of the whole subject it would seem that the "normal-dull person" is not feeble-minded but simply "dull." Being "normal" as far as the emotional part of his nature is concerned, he will get on fairly well and may become a valuable member of society, provided he is in the right milieu. Lack of work and bad company may make a derelict of him and, sooner or later, land him in the workhouse or in jail. What the normal-dull person needs is some training which will enable him to make himself useful in one of the many occupations in which a certain mental inferiority, far from being a handicap, is in reality an advantage.

One is apt to think that these borderline cases with character defects are to be found largely in the lower walks of life, but this is only seemingly so.

Simple mental tests in normal-dull persons rarely indicate the character and emotional fault in evidence. In some respects these conduct disorders when present are not dissimilar to those seen in the moron, although the pattern plan of the antisocial acts is obviously cleverer and more elaborate. The main difference in such acts of

the normal dull person and those of the psychopathic inferior is the presence in the former of a more enduring affect regarding the specific delinquency, and the field of delinquency does not spread over so large a field of activity. Then, too, the acts are more closely connected with the genetic instinct. In many it would seem as though the main first fault were not a disciplinary one, but the boy's unsuccessful repression of his too lively sexual fancy and desire. The general temperament of the normal-dull person is on the whole one of tendermindedness rather than the callous indifference of the so-called psychopathic delinquent. In the composite one would say the antisocial act of the normal-dull person is analogous to the heedless carelessness of the moron combined with a sexual tinge of the socially unstable plus the narrow transgressions of the petty offenses of the psychopathic delinquent.

CASE I.—The case which we shall first consider is that of a boy of nearly seventeen years, who was dismissed from preparatory school for failure in class and examinations, and sent for analysis because of his lying, cheating, dissolute expenditure of money, and general dilapidation of character and conduct. In early childhood he had two operations for the removal of adenoids and tonsils. He also had a slight attack of rheumatism. Both mental and physical development were slow. He preferred to play with boys two to three years his junior. In the home he was wilful, evasive and disrespectful. His teachers reported that he was a clear thinker but a slow worker and lacked mental concentration. At the time he came under analysis it was expected he would be able to enter college at the age of twenty. He was sluggish physically and mentally, even in the sports he liked. He seemed content to drift along in life without much imagination or ambition. Most frequently he blamed others for his faults. He had no natural fortitude in standing aches and pains and seemed unashamed to own to it.

Physical examination showed him to be greatly overgrown for his age, and of the dispituitary diathesis in makeup. Puberty was delayed until his fifteenth year. The revolt of independence at puberty was shown in crass disobedience, affectless indifference, and callous disregard for others. The sexual life naturally was caught in this imperfect development of his emotional life.

The psychologic test showed his mental age to be 16 years, 2 months, nearly up to his chronological age (16 years, 8 months). There was very little scattering shown in the tests. His basal age was 14 years, and he scored four successes out of a possible six in the average adult level, and one success in the superior adult level. The successes included interpretation of fables; differences between abstract words; repeating six digits backwards—which requires a heavy demand on attention besides an ability to manipulate mental imagery; and the code test, requiring also close attention, which must be directed inward since no stimulus to attention is present to the senses; in addition, steadiness of purpose is required. In the Trabue completion test he scored an adult performance. In the cancellation test he scored to the 14th year. He had the power of abstract thinking, ability to elaborate, and excellent visual constructive ability. His intelligence quotient was rated at 99, whereas the intelligence quotient for high school pupils who can get along easily in their studies is 110, which meant that our patient would have to study hard to make the higher grades. Some nervous instability was suggested by rather frequent embarrassed laughing, and his attitude at times was characterized by considerable uncertainty and lack of confidence in himself.

We have here a boy whose slight retardation in development brings him within the group of the normal-dull person. How much the dispituitary constitution is a cause is not easy to determine. It is certain, however, that as in most of such

cases, this boy's stable development rests upon the practical recognition that he is concrete-minded, and as such these individuals should be largely trained in skilled handwork or artisan crafts and professions requiring concrete application. After a short analysis he undertook to enter another preparatory school where he is now making fair progress both intellectually and in conduct training.

CASE II.—My second case is that of a boy in middle adolescence, who failed in his preparatory course for college, and dilapidated in character by cheating in examinations and seeking dissolute companions, which caused his dismissal from school. He was born of good stock and normal parents. The home life had been satisfactory. He had an approximately normal childhood in mental and physical development aside from a singular lack in mental concentration in all his school work, and ordinary educational methods held no appeal. At twelve years he grew rapidly and suffered from a severe facial acne. He was extremely resentful of correction both at home and at school and became more reticent and self centered. The report of his head master is pertinent, and makes the fault in his school record stand out in vivid outline; the report runs as follows:

"This is the boy's third year in my school. The first was wholly unsuccessful from the point of view of studies. He seemed immature and lacking in application, but he was good looking and winning, and made friends easily. He played the part of a girl in several shows, which attracted attention from some of the older students, and he was somewhat spoiled by his experience. He seemed to have the greatest facility in making friends with older boys of the less stable type; I have no suggestion of any impropriety; he simply ran with boys of the slightly sporty kind who were attracted by his good looks and good nature. I felt sure he would come out all right. During vacation his summer camp councillor gave him a good name.

"The second year the boy started well in scholarship, the work being review, but his standing fell off as he got onto new ground, though he managed to pass for the year and was promoted. He had C in English, mathematics and science, and D in Latin and French—not a very good record for a repeater. He began to take some interest in school activities, and was successful in making the paper on the advertising end. In things of this sort he shows his greatest ability; he can solicit advertising, act as assistant manager of a team, greet our athletic rivals, and attend to practical details connected with games.

"This year his scholarship has been indifferent from the start, two failures the first month, three D's, an E and a C for the first term. He belongs to what we call the lazy, self-indulgent, sophisticated group. No boy spends more time than he in hanging around the village and buying sweets, and this in spite of frequent admonition. Recently I found him with a couple of others on Sunday morning in the drugstore after their hour of closing—not a crime but a sadly unworthy while way of spending time. We are more concerned, however, with specific incidents. Last fall he was suspected several times of dishonesty in written work, and finally there was clear evidence of his having copied large parts of a mathematics test from another boy. He absolutely denied any fault when questioned, and when I talked with him he lied circumstantially and in detail, having a full explanation all ready. A few hours later he came to me and said he could not rest easy, and that he had cribbed. He confessed first that he had done such things once or twice, then pretty often. I talked with him in a sympathetic manner, and gave him encouragement. I thought this would have a good effect, especially as he wrote his father how fair I had been and how I had gone out of my way to straighten matters. We do not feel, however, that he is now wholly trustworthy, though we have no more proof; he has a roving eye during tests that bodes no good.

"Another thing came to my attention as follows: This boy got another, younger than he, to promise un-

der mild torture that he would do anything he was told for a given time. He then made the boy go with him to the room of a third boy, who held him while he undid the boy's clothing and otherwise acted indecently. Both of the younger boys were disgusted but rather terrified by the older boy with prestige of being an old boy in the school. When I talked with him about this he said he had done substantially what he was charged with, but thought it had been exaggerated. On sex questions in general I get little response. He has had some instruction at home, and says these things are not on his mind, that he occasionally tells smutty stories, "but no more than anyone else," etc. I have talked his case over in faculty meeting, and one man thinks the boy essentially coarse, and another says the older fellows consider him the worst influence in school. We don't want him back unless we can be assured that we can look for better things."

A psychologic test showed as follows: His chronological age at the time of the test was 16 plus years, his mental age 16-6 years; intelligence quotient, 103, indicating average intelligence. He succeeded with every test of the 12th year, therefore his basal age was 12 years. In the 14th year he passed four of the six tests, i.e. the vocabulary test; the induction test which is little if at all affected by schooling and which tests ability to generalize from particulars; the "problems of fact" test, and the arithmetical reasoning test. In the 16th year he succeeded with three of the six tests, namely, giving difference between abstract words; a problem, the statement of which must be comprehended and its conditions held in mind while it is being solved and in which constructive imagination is required; and the repetition of 6 digits backward which makes a heavy demand on attention. In the 18th year he passed three of the six tests, namely, repeated 8 digits, which indicates excellent rote memory; he got most of the thought of a difficult passage which was read to him; the third test with which he succeeded in this year was the "ingenuity" test. It requires practical judgment and a certain amount of inventiveness. As a summary of the tests, his performance showed he possessed average intelligence. Children with this degree of intelligence seldom have trouble as far as learning is concerned in the elementary school. In high school, however, they are likely to find themselves in "deep water" and are able to earn less than average marks. This boy had a superior memory span but recall memory was not as accurate.

We have here a fairly normal boy in physical development but with a slightly retarded mental development and the steady and insidious ingraft of moral defects. More intensive analysis showed an enormously distorted sexual fancy of a sadistic character. The situation was not so benign in correction as in the other boy of the foregoing record, nor was there the opportunity to painstakingly unravel the special fault afforded. The boy is obviously not sufficiently endowed mentally to make a good university training, nor will he be able to make a successful commercial career without a signal correction of his attitude in fair dealing with his associates. The unconscious or repressed sexual strivings are too dynamic in character formation to portend a healthy life without psychoanalysis. The boy's future is fraught with many pitfalls unless this be undertaken.

General Remarks.—In a summary review of the illustrative cases given in this paper we may say we have here the more or less benign manifestations of adolescent variations bringing the youths into conflict with the orderly routine of home, school, and society in general. The first case shows an emotional defect with slight intellectual retardation as well, and this double defect indicates how great is the amount of care and atten-

tion needed in handling such boys; while the second case has the handicaps of the first plus the potentialities of inborn sexual perversion requiring the most serious consideration.

The number of youths illustrative of these adolescent defects must be legion. Only the short-sighted arraigns these faults upon moral or religious defects rather than upon abnormal psychological trends. No doubt more earnest attention should be given to these variants, but the rôle they play may be quite as easily over-emphasized as the fault of giving them too little concern. A judicious attention and wise guidance of the three parties concerned—the boy, the parents, and the teachers—ought to bring about much more satisfactory results in future.

The question naturally arises, are there early evidences of primary faults in the instinctive life of these youths? To which one may reply positively, as shown in the cases here cited. Secondly, does one find evidence of these faults in the family stock or is it purely a congenital defect? The answer here is by no means so certain and positive. On the whole, however, I may say that several years of preoccupation with these boys, both in private and public school work, has shown that almost invariably one may find exhibition of the same trait character in the ascendants. In many instances the latter have lived their lives in much less exacting environments than their descendants and consequently have not been held up to the sharp scrutiny of a more rigid code of ethics. Even to-day in sparsely settled rural districts it is common to find many normal dull persons with social dilapidations classed as shiftless and "no accounts" or black sheep, who are permitted an astonishing range of liberties without the slightest apprehension of the general public as to its own safety or even discomfiture. They are often mentally ticketed by the community as not to be fully trusted in the responsibilities of life. Living a life of communal ostracism, they ultimately find themselves in almshouses and jails, or eke out a precarious existence at the hands of relatives or charitable persons. Often a vicious inbreeding intensifies the defect, and all sorts of degeneracies follow in the family stock. The whole subject makes an excellent one for intensive study on the part of all interested in the broader application of practical principles of mental hygiene. The subject is excellently begun in the epoch-making survey of mental disorders in Nassau County by Rosanoff.*

Detection and classification of these subnormal individuals are absolutely necessary, not alone because of the mental defect but because many of them are potential antisocial factors in the community with all the various aptitudes for delinquency noted in the text. Second, the character faults would seem to be on the whole independent of the quantitative estimation of mental defect, although the two are frequently correlated and the greater number of delinquents would probably be found in this group than in the normal group. Third, undoubtedly there is a great

need for schools, both private and public, to recognize the qualitative faults in such individuals and establish an education adapted to overcoming the same quite independent of purely an effort toward correcting the mental retardation. It should be somewhat along the lines that have been suggested in this and other studies upon the socially unstable, the high type of feeble-mindedness such as the moron, and for the so-called psychopathic inferiors.

A general pedagogical and training approach to this complex problem of the dull normal person is the immediate practical question, both in the field of his concrete-mindedness, and the training out of the character faults which are likely to occur far more frequently in this group than in the general run of abnormal adolescents. To prevent or train the dull normal adolescent we have need of the very best in pedagogic psychology. Singularly enough most problem pupils in the so-called normal schools are embraced in the equally handicapped though antipodal mental makeup of the concrete-minded and the abstract type. Unfortunately the schools as now arranged more or less exclusively screen out the concrete-minded and do not consider the abstract thinker as a real problem. Our system is so arranged that the importance of rote memory and the grasp of the symbol is overconditioned.

Let us sketch briefly some of the dilemmas of the rather pronounced type of the abstract-minded pupil. First of all he enters school rather overkeen for books and their ways of presenting thought. To him abstract work is the game above all. The actual concrete problems in symbolic studies are embraced par excellence in mathematics and language work. But he falls short in putting such clever means of thinking into an actual constructive plan of work. Things get in his way. He is usually inferior in physical equipment, and does not easily adapt himself to the larger boy group or in the play sports of the school. He is not a good mixer. The boys usually find his highbrowism spoils him for good fellowship, and he is apt to degenerate into a "greasy grind" and thus lose out in gaining an education in any large sense. But because of his excellent class standing he may still be the idol of the faculty and is often held up as an excellent example to the slow-witted members of his class much to his continued disadvantage in making class teams and getting into a more definite rapport with the athletic group. His difficulties are increased as he nears the end of his school career or when he actually enters upon active life work. Not infrequently he is encouraged to take up teaching as a profession, and if so he lends his moral support to a more fixed specie of symbol or abstract thinking. Thus we find the educational system has a tendency to limit its own objective until outside influences compel changes to a larger and more comprehensive plan of education. What usually is the after life of these rather narrow, sharp-pointed types of abstract pupils? Either they reform, in part, at least, by taking up the world's work, or they gravitate into office forces or skilled technicians of the business class. The world is filled with them. The more concrete-minded who

*A. J. Rosanoff: "A Survey of Mental Disorders in Nassau County, N. Y., July to October, 1916." Publication No. 9, National Committee for Mental Hygiene.

limp through the school curriculum get their innings on leaving school. The concrete world actively supplies them an enormous stimulus. One of my patients, at one time a noted football player and now a clergyman, said, "I never could fully understand the book work in undergraduate and theological training, but so soon as I got among men and their daily problems I was once more at home—the real work of the world to me is concrete and vital."

It is obvious, of course, that what one needs, as Dewey* points out, is to develop both attributes. The abstract thinker needs to fill in his empty rationalities with concrete work, while the concrete-minded needs to have his mind extra trained in the use of symbols. Both problems, if we are to fully meet the issues of education, are equally pressing. However, our concern here is to see whether we may not enlarge the capacity or adapt the too concrete-minded pupil. Every child is more or less interested equally in adventure and fairy tales. Their colorful and vivid appeal is for all. Why is it not possible to so ingraft the simple, natural, and appealing principles of symbolic thinking of childhood into ways of thinking upon school studies? Thus we may carry the concrete principles of work of the grammar school into the high school and college curriculum. In point of fact that is what is actually done with these dull-normal concrete-minded pupils when they are sent as educational problems to the cleverly arranged preparatory school. First of all the teaching personnel must be capable of diffusing its own vivid human interest in the subject to the slow-footed, plodding student—a sort of benevolent contagion of thinking is imparted. Then, too, the teacher should constantly add the vividness of concrete application to the symbolic thinking as he advances his subject. Teachers in all walks of life are too apt to consider illustrations as digressions and time-killers, and use them sparingly. If they but realized it the intellectual things which they wish to teach their auditors should have a warp of concrete presentation with a woof of symbolic thinking instead of vice versa; the dull-normal student would then stand a better show of getting on.

While we all know that the concrete dull-normal student can never be made a clever symbolic thinker, yet if we would but take more pains, extend and elaborate more slowly our advance in the development of such minds, many relatively benign states of despair can be removed and the others made more acceptable in life adaptations. These suggestions are offered to the teaching profession to work out by their excellent adaptive methods which everywhere they are putting into modern education.

Sexual Propagation of Trypanosome Disease.—Nattan-Larrier compares the venereal transmission of dourine and Chagas's disease, of which the former has long been recognized as venereally transmitted in the horse. The analogous transmission of Chagas's disease is only recently recognized; and compared with dourine the contagion is feeble.—*La Presse Médicale*.

IODINE IN THE TREATMENT OF GOITER.

By S. P. BEEBE, Ph.D., M.D.,

NEW YORK.

A FACT once established is not overthrown by subsequent progress. It may be neglected or relegated to a point of relative obscurity by the intense interest in other relations, but it has so stubborn a character that it can never be entirely replaced or forgotten. The intense interest which has been shown in the study of goiter in recent years has in many instances led away from one of the most fundamental facts in connection with the problem, and this has to do with the primal importance of the iodine content of the thyroid gland.

The relations which iodine has to thyroid function and to the development of goiter have been the subject of many experimental investigations, and quite diverse opinions have been expressed. From the standpoint of medical progress such interest is easily understood because it has been possible to measure certain factors accurately, and there is no more important subject in internal medicine than the relation of disordered thyroid function to disease.

It is most interesting to note that iodine-containing substances were used as medicine in the treatment of goiter long before the discovery of the element iodine itself, and that it was nearly a century after the discovery of iodine before its presence and very high relative content in the thyroid gland were determined. Empiric medicine not infrequently has been justified by later scientific investigation. One needs only to recall the origin of the quinine treatment for malaria, the use of mercury in the treatment of syphilis, and the history of digitalis to confirm this statement. The pressure to do something to relieve the sick is not a recent acquirement of human nature.

Baumann discovered iodine as a constituent of the thyroid gland in 1895 and isolated a substance from the products of acid hydrolysis to which he gave the name iodothyrene. This substance contained varying quantities of iodine from 9.5 per cent. to 15 per cent. The writer, following his method, has occasionally obtained a product containing as high as 20 per cent. iodine. This product was believed to be the active product, the characteristic agent responsible for thyroid activity, but further investigation has disproved these earlier conclusions. The discovery that the thyroid was peculiarly rich in iodine uncovered a most important fact, the full significance of which is not as yet completely understood. Since Baumann's time practically all tissues of the body have been analyzed for iodine, and thyroids from many different species of animals, the glands from the same species at different ages, different seasons of the year, and under different conditions of feeding have been carefully tested for this most important element. Different types of goiter in both man and animals before and after the administration of iodine in different chemical combinations have been analyzed for iodine. There has been a large volume of this iodine study and the conclusions are not in all respects in harmony. This is due in part no doubt to the variety of technical methods employed, and to the varying skill in the investigators.

Some of the most recent and most interesting studies along this line are those of Kendall, who has isolated a compound, thyroxin, containing 60 per cent. iodine, which he believes is the active and characteristic secretion of the thyroid gland. His conclusions in this matter do not seem to the writer to be in harmony with all the facts. As compared with the other tissues in the body the thyroid contains so much iodine as to make the other tissues relatively unimportant as iodine containers, and its constant occurrence, the avidity with which the gland takes up iodine, the remarkable changes in functional activity and anatomical structure which follow iodine absorption, indicate beyond any reasonable doubt the fundamental nature of the function which iodine plays in the activity of the thyroid gland. The following table shows the iodine content of the normal human glands in this region:

Weight of Gland	Milligram in One Gram of Gland	Total in Milligrams
23.3	0.473	11.02
22.5	0.79	11.02
24.75	0.46	11.38
16.5	0.34	5.61
19.5	0.15	2.92
32.25	0.40	12.10
17.0	0.31	5.27
22.0	0.31	6.82
24.5	0.23	5.63
26.25	0.14	3.67
26.5	0.40	10.60

It is not possible within the limits of this article to discuss in detail or even indeed to outline the nature of the various theories which have been put forward by investigators in explaining the action which iodine has in the thyroid gland, but it is worth while to summarize what seem to be definite conclusions that are subject to little controversy and are compatible with all the different investigations of moment.

1. The thyroid gland is the richest in iodine of all the tissues in the body.

2. The thyroid in its normal natural state contains a relatively higher quantity of iodine per gram of gland than a goitrous gland.

3. The thyroid has the ability to store iodine within limits from practically any iodine compound that is absorbed into the circulation.

4. The iodine content is rapidly increased in many forms of goitrous glands during iodine administration.

5. There is a wide variation in the limits to which iodine may be present in the gland compatible with health.

6. While in very young animals or in those on a restricted diet it would appear that a thyroid without iodine may have sufficient function to keep the animal in health for a time, yet the evidence strongly indicates a relation roughly quantitative between the iodine content and the physiological activity of the gland extract.

7. While the iodine is normally contained in the gland colloid, glands that have become almost entirely cellular as a result of hyperplasia retain the power to absorb and store iodine.

8. A variety of iodine-containing compounds is present in the gland extract.

9. The absorption of iodine frequently assists the reversion to more nearly normal histological conditions in glands that have become the seat of cellular hyperplasia.

Quite a variety of iodine-containing substances have been prepared from thyroid glands. These differ somewhat in their chemical structure, solubilities, and physiological action. Without doubt some of them are not to be understood as natural products of the gland activity, but are rather to be looked upon as cleavage products of varying size obtained through the hydrolytic action of the particular acid or alkali used for the purpose. It need not be supposed that all of them normally are formed and enter the circulation from the living gland merely because they may be obtained in the laboratory by a drastic chemical action, and in this paper there will be no further discussion of their significance.

In the writer's experience three different forms of iodine answer all the requirements for therapeutic purposes. These are potassium iodide, ferrous iodide, and thyroid extract. The writer has never been able to find any advantages in the large array of ointments, organic compounds of iodine, or so-called colloidal preparations of iodine now available in the market. Kendall has recently isolated what he believes to be the active iodine-containing element from the thyroid, thyroxine, and claims for it specific action in certain types of thyroid disease, and his published results certainly seem to substantiate these claims. The writer has had no experience with it and cannot, therefore, give any estimate of its usefulness.

The total quantity of iodine in any thyroid gland is very small in comparison to the amounts usually given as a daily dose for therapeutic administration. In general, the doses used ordinarily are quite unsuited in goiter. The variation in the sensitiveness of different patients to iodine is well known, and this is particularly true of goiter patients. The dangerous consequences of large doses of iodine have been repeatedly emphasized, and the caution is indeed a needed one. Doses of ten, twenty, or thirty grains of potassium iodide are frequently given three times daily in luetic conditions, and the profession has gained most of its experience in iodine administration with such maximum dosage. Such doses are dangerous in any form of goiter. The writer has seen a considerable number of patients during the last ten years in whom these large doses have induced very active thyroid toxemia. Nevertheless, iodine is the most valuable single medicine, and the most universally applicable to all forms of thyroid disease.

There is practically no dispute that iodine should be given in some form to patients having simple goiter, or the early stages of endemic goiter. The dose must be small and long continued. The initial doses should be one or mostly two grains of potassium iodide three times daily. After four to six weeks at this rate the dose may be gradually increased in some cases to five grains three times daily. The writer rarely has found any occasion to exceed this dose. In this respect the writer differs radically from the advice given by McCarrison, who gives to such patients five minims of the tincture and five grains of the potassium salt as the initial dose and increases gradually to three or four times as much. Such dosage may be advisable and suitable for the natives of India, where McCarrison has gained his experience, but it cer-

tainty would cause havoc on the patients seen by the writer in New York City. If the iodine effect is desired in such cases it can be obtained readily by the use of the potassium salt, and the writer has found no occasion to use any ointment or tincture externally. Such applications are irritating, disfiguring, and the absorption of iodine from them is uncertain and irregular. Whatever iodine can do for the gland can be done by the administration of the potassium salt. The writer gives the caution, however, that iodine is only one factor in the treatment, and the general hygienic care of the patient, especially from the standpoint of infections and gastrointestinal disorders, must not be neglected. Such emphasis is necessary, for it is still too frequently the opinion that iodine administration alone answers the physician's responsibility toward his patient in cases of simple goiter. Even Crotti, in his recent book, states: "We may say that medical treatment of simple goitre is contained in this one word—iodine."

The length of time iodine administration must be continued in somewhat a matter of dispute. At times the response of the gland toward iodine is prompt, and three to six weeks' treatment may show very marked results, but it may not be so prompt, and the writer in many cases continues iodine administration for periods of a year, and even two years, in small doses, with occasional interruptions. Even after normal conditions of health and gland have been produced, it is wise to continue the iodine in small doses. This is especially true in those cases that occur in young women who later marry and then become pregnant. During the pregnancy two grains of potassium iodide three times daily will keep the thyroid function up to normal, and the patient has less toxic manifestations. In many cases the iodine effect is slow, and months will be required to effect the desired changes in the gland. A further point of importance in iodine administration to thyroid patients is the necessity of keeping the patient under observation, particularly in the earlier periods of the treatment. The optimum dose varies so much with the different types of the disease that only by constant observation and careful trial can this be determined.

Iodine administration to hyperthyroid patients is the subject of great variation of opinion on the part of the many students of this problem. Some writers condemn its use in the most positive terms and issue the warning that iodine must never be given to hyperthyroid patients. Others assert that it may be given in minimum doses under constant supervision. In going over these statements in the literature it seems probable that the actual basis for the conclusions has been theoretical considerations and preconceived notions rather than careful clinical observations. The precise relation which iodine bears to the Graves' syndrome is not as yet understood. Proceeding from the thesis that the functional activity of the gland is proportional to its iodine content, and the observation that the iodine content is rapidly increased by iodine administration, it has been suggested that iodine may be given in doubtful cases for diagnostic purposes. If a few grains of potassium iodide are given in a doubtful case of hyperthyroidism

and the symptoms are augmented, it may be concluded, according to this hypothesis, that a state of hyperthyroidism actually prevails.

The logic of this argument is so attractive that it has been a factor in restraining a useful therapeutic method. The determination of the quantitative relation between iodine content and physiological action was one of the points in the experiments of Hunt and Seidell, who investigated the protective power of thyroid feeding to acetonitril poisoning in mice. Results of this character are obtained by feeding thyroid extract of an alien species to an otherwise healthy animal and, while they may be accurate within the conditions of the experiment, it is hardly justifiable to apply them literally to an entirely different set of conditions with so many obscure factors as obtain when the human animal is apparently poisoned by an excessive action of his own gland. We do not know as yet to what degree the thyroid is primarily at fault, and to what degree it is reacting in a mechanism of defense to stimuli, both nervous and chemical, which reach it from without. It seems reasonably certain, however, that the conditions which govern the therapeutic administration of iodine to human patients with varying types of hyperthyroidism are not fully covered by the interesting syllogism cited above.

The hyperthyroid gland is poor in iodine. Several years ago the writer made iodine analyses of many such glands, and as compared with the normal gland, containing 0.364 milligrams, an average of 0.095 milligrams of iodine per gram of fresh gland was obtained from the hyperthyroid glands. In at least some and at times all portions the hyperthyroid gland is the seat of very definite hyperplasia. The purpose of treatment is to restore the gland to normal, both in structure and function. Iodine must be taken up by the gland to accomplish this end. If not given as a medicine the iodine in the food supply must be depended upon for this purpose. The sensitiveness of some hyperthyroid patients to iodine administration is well known and the doses must be regulated carefully, but the desirability of giving iodine as a medicine to patients in this group cannot be determined by animal experimentation. This matter can be determined only by clinical use on the diseased human animal.

In the writer's experience iodine is one of the most valuable therapeutic agents we have in the treatment of the hyperthyroid forms of goiter. As in the case of any potent drug, injury can be done with it. So can we do injury with digitalis and salvarsan. During the last ten years the writer has treated a large number of cases of hyperthyroidism, and with most of them the administration of iodine has been a part of the treatment. There is no danger in so doing if the dose is properly regulated. The extreme sensitiveness described by some writers is a rare event. If the dose is properly regulated there need be no fear of iodism or iodine Basedowism. At rare intervals a patient will be encountered whose sensitiveness to iodine is so marked that only minimal doses, a fraction of a grain, can be given, but it should be remembered that the total quantity of iodine in a normal adult gland is very small, from one-third to one-half a

grain. In the earlier stages of the disease and in the acute fulminating types, smaller doses are to be used than in the later stages and chronic forms.

In young women with active hyperthyroidism extending over a short period of time the beneficial effects are slower to appear and smaller dosage must be used than in the later stages of the disease when its character has changed somewhat. A dose of one-half to one grain of potassium iodide three times daily is enough to begin with, and the dose must be kept at that amount for several weeks, perhaps two months, before increasing it. Overdosage will promptly show itself by the increased disturbance it causes.

In those patients, for the most part young women who have the typical Basedow condition from the outset in severe form, *i.e.* their hyperthyroid manifestations have not been grafted upon a previously developed simple goitre, iodine must be administered with great caution. Unless given in minimal doses the possibilities for doing harm are greater than in any other type of the disease. Small doses, one-half grain potassium iodide twice daily, rarely cause any disturbing reaction, and if continued with occasional interruptions, over some weeks or months, it appears to the writer to be of benefit for the majority of these patients.

The most pronounced effects of iodine are often seen in the thyroid disease, occurring in women who have had the disease for several years, often for eight to twelve years. They usually have the cardinal symptoms, exophthalmos, goiter, tachycardia, and tremor, well developed. They are usually constipated and have a history of much gastrointestinal disturbance, severe headache, high blood pressure, congested inflamed pharynx, the skin of neck and chest pigmented, and a very pronounced tremor.

In patients of this type iodine often acts like a specific, and in a few days the entire clinical picture has changed for the better. No other medicine can replace iodine in this group. The drop in blood pressure, slowing of the heart, diminution in tremor and extreme restlessness, relief from the toxic manifestations are so prompt and decided, and the general change for the better so promptly follows the proper administration of iodine, that it seems at times a more simple matter to influence favorably these old worn-out cases than it is to get equally good results in the younger stages of the disease. From the operative standpoint they are bad risks, and even if the patients survive, their condition is little, if any better, and frequently, indeed, it is worse.

Every case of hyperthyroidism subjected to operation is a medical case before and for a long time following the operation. If this procedure is not followed, the beneficial effects of an operation will be largely lost. In the recurrent cases, as well as those treated with the x-ray, iodine is an essential part of the treatment.

Glands that have been the seat of hyperplasia and have been the origin of hyperthyroid symptoms do not always regain the ability to maintain normal function on the iodine supply of a mixed diet, and not infrequently they may need additional iodine supplied occasionally for a period of some years. This is particularly true in case the pa-

tient has unusual demands on the thyroid apparatus, such as pregnancy or infectious disease.

In this paper emphasis has been placed upon the use of iodine in the treatment of hyperthyroidism. In the writer's opinion the disease will not be properly treated until the value of iodine and its proper administration are learned by the medical profession. However, it is not the whole of medical treatment. Other factors may be of equal or even greater importance, but they cannot be outlined in the limits of this paper.

116 EAST FIFTY-THIRD STREET.

SOME MEDICAL ECONOMICS PROBLEMS.*

BY EDWARD H. OCHSNER, B.S., M.D., F.A.C.S.

CHICAGO, ILL.

ATTENDING SURGEON, AUGUSTANA HOSPITAL.

A PRACTICAL farmer does not buy a horse just because it happens to have a high sounding name. About the first thing he does is to look at the eyes to see whether the beast is blind or not and to determine whether it is true or not. The next thing he does is to run his hands over the joints to find out whether it has a spavin or ringbone, or steifel; then he tests its wind to determine whether or not it has heaves, and finally he looks at its teeth to see whether it is as old as Methuselah or not. The story is told of a city man who became an agriculturist. About the first thing he did was to buy a horse. He was shown a gentleman horse by the horse dealer. It was not worth much but he bought it and paid about twice as much as it was worth, principally because the horse jockey kept calling the beast by the not altogether appropriate but very euphonious name of Lady Clementine. This is about the way we of the medical profession have in the recent past been asked to buy welfare schemes of all kinds. If such a scheme has had either the word Charity, Philanthropy, Health or Welfare interwoven into its title, we, of the rank and file of the medical profession, have been asked by some of our high-brow near-medical leaders to buy without further examination. It is about time that the medical profession of America use as much judgment and discretion when it goes into new schemes as does the ordinary plain farmer when he buys a horse.

This is the age of standardization. We have standardized medical colleges, standardized surgeons, we are soon to have standardized hospitals and we are creditably informed that the lay Health Commissioner of Detroit is trying to standardize the stomachs of its citizens. It occurred to me recently that it might be a good idea if we would standardize all these schemes that are being presented to us. Give them the acid test and if they are not true gold, let us not buy them even if they are called Lady Clementine.

I think the medical profession ought to oppose all schemes (1) *which are not absolutely necessary*, (2) *which introduce new evils*, (3) *which advertise a few at the expense of the many*, (4) *which appropriate without fair remuneration the skill, knowl-*

*Address delivered before the North Side Branch of the Chicago Medical Society on April 7, 1921. An address of similar scope was delivered before the Northwest Branch of the same society and published in the *Illinois Medical Journal*.

edge and time of the physician, (5) which are palliative instead of preventive or curative, (6) which further place medical men under lay supervision and control, (7) which unduly interfere with the individualism of the medical man or are paternalistic, (8) which have a tendency to pauperize the public and thus destroy the self-respect and self-reliance of the people.

Let us revert and briefly consider each one of the above eight tests.

1. I believe that the medical profession of America renders better service to its fellow men than does any other group of its citizens. I believe that the average American citizen has better medical care than has the average citizen of any other country on the globe. If these two statements are true, what is the need of any of these new fangled schemes? Of course, we must have progress, but

2. Let us be very careful in adopting new schemes to see that they do not introduce new evils—evils which may be greater than those we are trying to correct. I heard an English publicist and lecturer speak in Chicago some eight or ten years ago and he described a little scene that he had witnessed the day before on Wabash Avenue as rather typical of American life and thought. He said he was riding on the front platform of a street car. It was a slushy, blustery, snowy, muddy day and the conductor stopped at a crossing at the side of a mud puddle and rather querulously ordered the passengers to "Step lively please, step lively." The Englishman said he felt like saying "Don't look where you are stepping, but keep a-moving." It is about time that we physicians look where we are stepping. Make sure first that we are going in the right direction before we adopt any scheme. Then, if it proves good, adopt it, but let us not keep a-moving just for the sake of moving.

3. Let us analyze the real fundamental reasons for the establishing of free clinics and dispensaries in Chicago as elsewhere. You will find four reasons—two are legitimate and two are not. The legitimate ones are to provide proper medical care for the sick poor, and to provide teaching material for medical students. The illegitimate ones are for the purpose of advertising a certain doctor or group of doctors, or to act as a feeder for a certain hospital. When we adopt new schemes let us be careful that they are for the benefit of the rank and file of the profession and the people and not for the aggrandizement of a few. A very large per cent of the dispensaries of Chicago should be abolished. They are detrimental to the profession and to the citizenship of Chicago. This is not popular doctrine but it is true just the same.

4. We should also oppose every scheme which appropriates the time, skill, and knowledge of physicians without just, fair, and reasonable remuneration. Why? Because anything which continuously works to the disadvantage of the medical profession will in the end work to the harm of all the people of this country. Next to stability of government, honesty of administration, and general intelligence of the people, the welfare of a nation depends more upon the quality of medical service which is rendered to its citizens than upon any one other thing. The longevity, health, efficiency, and happiness of a people depend more upon the

integrity, ability, and industry of its medical profession than upon anything else. If these two postulates are true, and I think they are, then anything which hinders medical progress and which will have a tendency to prevent suitable young men from entering the profession is inimical to the best interests of the whole nation.

5. We should oppose every scheme which is a palliative instead of a preventive or curative. It is an axiom in medicine and surgery and should be in political economy that a palliative must not be used continuously for any considerable period of time unless the case is hopeless. These people who want to reform every one except themselves are continually advocating the continuous use of palliatives and this is a serious economic mistake. We physicians have learned better. We use morphine only to bridge over a period of short stress or to alleviate a hopeless condition.

6. We should oppose any scheme which has a tendency to further place medical men under lay political supervision and control. Medical men are being more and more dominated by laymen. This is a bad thing for the medical profession and a very serious obstacle to medical progress. Our hospitals are being more and more dominated by lay boards; our medical colleges are virtually completely under the control of laymen. Quite a number of our medical schools have deans who are not medical men, who cannot practise medicine in the State in which they are deans because they are not medical graduates. Another group of our medical deans, while they are graduates from medical schools, are unfit to practise medicine because they have had no practical experience in the practise of medicine. A very large group of our medical teachers are not medical men and while the old system of ownership of medical colleges by physicians had many objections, the new system has many objections which are even more serious. Our national, state, and county institutions with their thousands of patients are controlled by lay boards. In Europe, where Compulsory Health Insurance has been in force, this control is so menacing that medical progress has practically ceased. Frederick L. Hoffman is reported as having found a very amusing incident in his recent investigation of the workings of the Compulsory Health Insurance act in England. An English panel doctor prescribed fifteen capsules for a patient, but the patient got well when he had taken nine. This physician was called before the lay board, censured and fined because the lay board claimed that he should have known that the patient needed only nine capsules for his recovery. How would you gentlemen like to have some lay board appointed by Hinky Dink, Bath-house John, or John the Pow, or some other group of equally powerful politicians in this city, any one of whom has more political influence than all of you combined, tell you just what you may and may not do in the practice of medicine?

7. It is time, gentlemen, that the medical profession wake up. I am not a pessimist but the medical profession is to-day facing the most serious crisis that it has ever faced in the history of American medicine and it is facing it partly because of the general unrest among the people and partly because of muddle headed leadership. Most of these

schemes interfere with the individualism of the medical man. There can be no medical progress without individualism and without individual liberty. In political economy I believe in *voluntary cooperative individualism*, in other words, *democracy*, as opposed to *socialism and autocracy*. I am opposed to each and every one of the fifty-seven varieties of socialism because it interferes too much with individualism and dampens personal enthusiasm and incentive. I am opposed to autocracy for much the same reason.

8. We should oppose any scheme which has a tendency to pauperize the public or which robs people of their self-respect and self-reliance. Practically every eleemosynary institution is evidence of some fault in our economic system. It may be necessary now but our supreme effort should be to make all such institutions superfluous. We must have certain charitable institutions to-day but outside of charitable institutions for mental, moral, and physical defectives, who are unable to provide for themselves, the time should come and must come and will come, if we progress in civilization, when there will be no other charitable institutions because charitable institutions, no matter how carefully managed, have a tendency to take from independence its proper pride and from mendicancy its salutary shame. Shakespeare said very well, as he always said very well,

"Who steals my purse steals trash; 't is something, nothing;

'T was mine, 't is his, and has been slave to thousands;

But he that filches from me my good name

Robs me of that which not enriches him

And makes me poor indeed."

If Shakespeare had lived in this present day with all the innumerable welfare schemes in operation and contemplation he would have added in very much better English than I can command the following thought: And he who deliberately robs any man of his self-respect and self-reliance is infinitely worse than even the thief or the blackguard. He is an enemy to society and a menace to free institutions. Free institutions depend upon a self-respecting citizenship and many of these welfare schemes rob men and women of their self-respect and self-reliance.

In this connection let me read just one illustration from many which could be cited. Several months ago the wife of a public school teacher, suffering from a lacerated perineum with a very pronounced rectocele, came to me with the following story: Has had six children, youngest about six months old. When seven months pregnant with the last pregnancy, she decided to go to one of our largest quasi public hospitals to be confined, because this hospital was under the management of a religious organization of which she had been a member since childhood. She was examined by one of the hospital staff, told that she had a severe rectocele and an immediate operation was advised. She consulted her brother-in-law, a physician, who advised against the operation at this time and told her to wait six months after the delivery and then see me about repair work. In spite of the most persistent urging of the hospital physician, she refused operation, was delivered six months ago and

a few days before I saw her, the follow-up nurse from the above hospital called on her and told her that she ought now to have her repair work done and that a certain prominent gynecologist had agreed to do it for her free of charge; instead, she came to me for examination and advice.

I operated on her a few days later. On examining her to-day, two months after the operation, I find the result perfect and the patient profuse in her expressions of gratitude for having been so completely relieved of the constipation and rectal trouble and in to-day's mail I received a letter from her husband, from which I quote the following: "Your statement was received a few days ago. Please accept my thanks for its amount, associated as it is with the highest grade of service. Thanking you with all my heart for what you have done for her and my family, I am, very gratefully yours."

I am not reading this letter to throw a bouquet at myself. I am simply reading it in order to be able to ask you whether you do not think that this patient was better off because she came to me and because she paid for her operation than if she had gone to this hospital, had had a free operation by a gynecologist who spent much time and money in acquiring the education and training which enabled him to do such an operation. What moral right had that hospital to donate this doctor's skill, knowledge, and time and give it to the wife of a teacher in our public schools? If our public schools do not pay enough so that its male teachers can provide medical care for their dependents, so that they may be and grow up as self-respecting free American citizens, it is time that we raise the salary of the public school teachers. What the men and women who are doing the work of this country want is not charity but justice. They want the privilege of having for themselves and their families the doctor of their own personal choice. They do not want to be pauperized, and practices such as above cited are nothing short of indefensible.

The activities of medical men, as medical men, can be classified into three functions: First, sanitation and public hygiene; second, the teaching of personal hygiene, and finally, the treating of disease. The first is distinctly the function of the State and the last is distinctly the function of the private practitioners of medicine. If any one has found anywhere in the writings of any of the gentlemen who are trying to make us swallow Health Insurance, Health Centers, and what not, the above fundamental classification and distinction, I would like to have a copy of it and I will thank you for it. They do not seem to be able clearly to comprehend that the State is the only agent that can really look after sanitation and public hygiene and that private physicians are the only ones who in the long run efficiently and effectively treat the sick. Why is it that in 145 years of existence of this republic nothing has ever come out of a government controlled institution that has materially improved the treatment of the sick? Here again if you can find a single exception I would like to have it. During the time of the existence of our republic approximately 1 per cent. of the citizens of this country have been under the medical care of the nation, State, county, or city authorities and yet not one single thing in the improvement of the

treating of disease has come out of these activities of the government. To-day there are approximately 1,000,000 people under absolute medical control of the above governmental agencies. What are they doing to improve the treating of disease? Absolutely nothing. Why? Because just about the time a medical man gets warm in his seat in a medical job and gets really interested in a certain line of work, he has to move on. Some lay bureaucrat down in Washington or Springfield pulls the string and the doctor has to move and the result is that after a few such experiences the doctor loses his interest and enthusiasm in treating the sick and he becomes interested in the only things that are permanent in government medical service—fawning for favor and political advancement, paper work, statistics, and public hygiene and sanitation. This is very well so far as it goes, but it does not cure the sick or make for greater efficiency in the treatment of disease. If you or I had the results in the treatment of empyema that occurred in some of our training camps we would have to go out of business. I have practised surgery for twenty-seven years. I have lost some empyema cases, but I have never had an acute empyema case which I operated on primarily that did not heal promptly without a secondary operation. Not one.

The teaching of personal hygiene is a function that may be equally divided by the State and private practitioner, but the treating of the sick is distinctly the function of the private practitioners of medicine. He who thinks that the successful practice of medicine and surgery depends entirely upon the ability to make a correct diagnosis, knowledge of the action of drugs, and a certain skill in the handling of surgical instruments, is as far wrong as he who thinks that all that is worth while in life is money and what money will buy. While money is needed in our modern economic system to procure the necessities of life, the finest things in life, such as true friendship, true love, and self-respect, cannot be purchased with it. So with the practise of medicine and surgery. To make it really worth while, the above requirements must be supplemented by an untiring devotion to detail and duty, a degree of personal sacrifice unknown in any other vocation in life. These coupled with the other things alone can secure that respect and confidence on the part of the patient so essential to recovery from a critical illness. How many times has the real true physician not been told by his patient after a desperate illness "Doctor, the only thing that kept me alive was that I just knew you would not let me die," and do not make the mistake of thinking that this is necessarily the twaddle of a weakling. Every really great physician has been told this time and again by some of the finest and strongest of his patients, who in time of severe illness and temporary physical weakness, needed some one stronger than themselves to lean on. This is one of the chief reasons why the attempt to treat the sick by impersonal, wholesale, commercial methods, always has been and always will be a failure, relatively speaking.

In the *American Labor Legislation Review*, vii., 1, page 54, March, 1917, Dr. Frank Billings wrote as follows:

I am unequivocally in favor of compulsory insurance

and the protection of maternity. That, I think, must be the attitude of any one who studies the question of illness in its relation to economic conditions. I am in favor of them, too, because our present method of managing the sick poor is about as bad as it can be. While we endeavor in every way to alleviate their sufferings and to put them back at work, our methods are loose. There is no unit of efficiency. The great number of hospitals and dispensaries which exist are said not to be enough, because they cannot take care of all the sick poor; and yet, from the standpoint of what would be necessary if we controlled the sources of disease, they are too many.

To my mind health insurance is going to be one of the best measures of preventive medicine. Under its stimulus the time will come when every community, to economize its taxes under this law, will see that there are practically no patients suffering from typhoid fever within its limits. We will have no smallpox; diphtheria will be diminished; everything known to be communicable will be diminished and many of the diseases incident to some confined, chronic affection will be removed. Such results will not be achieved except by some measure of State supervision, and I know of no State supervision which will equal state compulsory insurance.

I would like to have Dr. Lambert describe a little better the provisions for an inquisitorial body over all the health insurance work. You know, and I know, that we do not do our work well unless there is some incentive, something to make us do it properly, and so I think that in this bill there must be something of that kind.

If the gentleman who wrote the above needs an inquisitorial body to stand over him in order that he may render the best possible service of which he is capable, I am just plain sorry for him. In the last thirty years I have learned to know hundreds of American physicians and my experience is that the great majority of them have a well-developed, active, perfectly normally functioning conscience, a much better monitor I believe than a lay political straw-boss would be. In addition I would like to know by what process of reasoning or stretch of imagination the gentleman arrived at the conclusion that any system of Compulsory Health Insurance now in operation or in contemplation would be "one of the best measures of preventive medicine." To the contrary, about the best and only thing that can be said in favor of Compulsory Health Insurance is that it might temporarily be an economic palliative. That was probably the theory on which Lloyd George acted when he had the Compulsory Health Insurance law passed in England. The opiate is already beginning to wear off and the unrest in England is undoubtedly greater than it would have been had this palliative never been employed.

On Dec. 2, 1920, the gentleman who wrote the above quotation from the *American Labor Legislation Review* (Dr. Frank Billings) delivered an address before the North Side Branch of the Chicago Medical Society as reported in the *Journal of the American Medical Association*, Feb. 5, 1921, lxxvi., 6, page 352.

Compulsory Health Insurance, I believe, would be unsatisfactory to the people it is intended to benefit. In the main, it is class legislation, which usually brings injustice to some other class than those it is intended to help. Under Compulsory Health Insurance the chief sacrifice made in service and money would apparently fall upon the medical profession. It is intended to benefit the working class, many of whom earn as much or more in wages than the average annual income of the private practitioner. In my opinion, its alleged advantages to the laboring class do not solve the prob-

lem of better and more efficient medical service for the people whom it is intended to benefit. Its application will be more likely to degrade the members of the medical profession who become its servants. This derogatory influence on a part of the profession is most likely to be reflected on other physicians in the community with the resulting deterioration of medical service to the whole population. There is an axiom which is related to all schemes intended to benefit the public health. It is this: The chief dependence for the conduct of the necessary ways and means to improve health and lengthen life must be placed on the medical profession. I think it may be said that the majority of the medical profession is opposed to the statutory enactment of Compulsory Health Insurance.

After four years of enlightening missionary work by some of the opponents of Compulsory Health Insurance note the change of front. But then he goes on in the next three pages and describes the new panacea for all medical ills—Health Centers. I wonder, gentlemen, whether we have not a right to conclude that this gentleman is no longer a safe advisor for the American medical profession on matters of medical economics? I leave it to you to judge. Health centers, according to my humble opinion, is the same old baby with a new name and a couple of its feet cut off, and one of the feet is not quite severed either. He says that health centers are not compulsory. No, not until you adopt them. Compulsory Health Insurance is not compulsory either until you adopt it. The only difference between the health center and Compulsory Health Insurance in this regard is that you make the health center a matter of home rule and local conditions, but when you once adopt the health center it is practically just as much compulsory as Compulsory Health Insurance. Another feature that is actually cut off is that there is no provision for paying indemnity to people who are sick or out of work. But what assurance has the medical profession that if it should adopt this baby with a new name, rear it with loving care and kindness, that it might not turn out to be a baby newt or a baby salamander and that within five or ten years those feet might not grow out again? We cannot tell. Let it in once and you will get the same old baby back that we have been fighting for six years and that this gentleman has himself disowned.

I met one of my colleagues in the hospital the other day and he said to me, "Why do you not get in the bandwagon? Why do you not adopt this makeshift scheme proposed at the North Side Branch? I know it is only a makeshift, but you had better adopt it rather than ultimately submit to Compulsory Health Insurance. *You know we sometimes have to compromise with the devil.*" My answer was "No, doctor. The minute you compromise with the devil you are lost. We are in the right and I am a firm believer in the ultimate victory of the right." There is only one real antidote for all of these uplift schemes, ladies and gentlemen, and that is better and better and ever better work on the part of private physicians, be they either general practitioners or specialists. That is the only antidote that is worth considering. The others are all makeshifts, they are all compromises. Individual effort and private enterprise have done wonders for the science and art of medicine in this country in the past and I believe they can be relied upon to meet any and all conditions that may arise from time to time in the future.

METABOLIMETRY IN HYPERTHYROIDISM.

By HENRY R. HARROWER, M.D., F.R.S.M. (Lond.).

GLENDALE, CAL.

THE so-called "basal metabolism," or heat production of an individual at the lowest level of cell chemistry can now be determined with considerable accuracy by indirect calculation from the data of the gaseous exchange. The latter become available through determinations with comparatively simple respiration apparatus, and the estimations are made fourteen or more hours after the taking of food, at complete rest, whereby the stimulus to heat production incident to muscular activity or digestive changes is avoided. As few pathologic conditions that are not easily differentiated from hyperthyroidism show a rise in the basal metabolism, this feature serves as one of the most striking and characteristic manifestations of overactivity of the thyroid. Thus a novel index of the intensity of thyroid intoxication has been added to the hitherto recognized symptoms, including tachycardia, nervousness, loss of weight, and tendency to increased sweating. The foregoing editorial expression from the *Journal of the American Medical Association* aptly expresses the gist of this phase of the subject.

To DuBois, of New York City, is due the credit of pioneering metabolimetry in this country, though evidently the basic idea was first thought of many years ago by the German physician, Magnus-Levy. From that time on there accumulated a voluminous literature on this particular subject, but practically nothing appeared in American medical literature until 1916. At the present time metabolism studies are quite fashionable, and metabolism laboratories have been established in many parts of the country. The simplification of the calorimeters, or "metabolimeters," as they are beginning to be called, has facilitated the work and the complicated estimations of times gone by are now very much more convenient. As an editorial writer in the *Journal of the American Medical Association* said, in commenting some years ago upon DuBois' first paper: "At the present time (that is in 1916) the scientific status of the treatment of exophthalmic goitre is about at the point where we would be with diabetes if there were no laboratory tests for glucose and the acetone bodies."

The accurate technique of metabolimetry need not be discussed here. (The reader is referred to the papers of DuBois, Benedict, Means and Aub, and to the more recent books on laboratory procedure.) Briefly, the method consists in determining the gas exchange with the Benedict universal respiration apparatus (or modifications of this basic calorimeter), and from these data the heat production is calculated in relation to the body surface, which, in turn, may be conveniently determined by DuBois' height-weight chart. The calorific value of oxygen is used to estimate the respiratory quotient obtained.

According to DuBois, exophthalmic goitre stands out *par excellence* as a disease of increased metabolism, and the increased metabolism stands out as the chief symptom of hyperthyroidism. The determination of the heat production seems to afford

the best index of the severity of the disease. An increased basal metabolism is found with great regularity in exophthalmic goitre, and in severe cases reaches a level found in no other condition. All other diseases in which metabolism is increased are easily distinguishable from exophthalmic goitre, and they never approach the extreme found in this condition.

Measurements made by DuBois with the Benedict calorimeter, and confirmed by others, are highly significant, and inform us that very severe cases of hyperthyroidism show an increase of as much as 75 per cent. or more above the normal average, while in severe cases the increase is 50 per cent. or more, and in moderately severe and mild cases, 25 per cent. to 30 per cent. In a few mild, and several atypical cases, or cases in which operations have been performed, the figure may be within the normal limit. In the serious cases the warmth of the skin and the sweating can be accounted for entirely by the necessity for increased elimination of heat. At least a part of the tachycardia must be due to the increased metabolism, and perhaps it might be possible to reproduce the extreme tachycardia, cardiac enlargement, emaciation, and mental irritability, if we were able to stimulate so notably the metabolism of a normal individual for twenty-four hours a day over a period of months or years.

The most comprehensive studies on basal metabolism in exophthalmic goitre are those of Means and Aub, of the Massachusetts General Hospital. Quite full bibliographies accompany these papers. Another student of this aspect of hyperthyroidism, McCaskey, of Ft. Wayne, Ind., emphasizes that there is a close quantitative parallelism between the thyroid secretion and metabolic weight, and that the estimation of the latter by means of the oxygen consumption, therefore, may be relied upon with certain reservation as an accurate index of the activity of the thyroid gland. The isolation and identification of thyroxin and its complete chemical study by Kendall, of the Mayo Clinic, together with its physiological and therapeutic study by H. S. Plummer of the same institution, have placed the entire subject upon an accurate and almost mathematical basis. McCaskey believes that we may confidently proceed on the following assumptions: (1) That the symptoms of hyperthyroidism are due to quantitative variations of thyroxin in the body cells; (2) that the present fundamental phenomenon which dominates the entire clinical picture from cretinism to "Basedowism" is a perversion of metabolic rate; (3) that this metabolic rate has an absolute equivalent in accordance with fully established physical laws in the heat production of the entire mass of body cells; (4) that this heat production is essentially a process of oxidation and is equivalent to quantity of oxygen consumed, the latter being regulated by and dependent upon the metabolic rate; (5) that it is now possible with the comparatively simple Benedict Respiration Apparatus to determine clinically the oxygen consumption over a sufficient period of time, say five to fifteen minutes, with sufficient accuracy for all clinical purposes, and finally (6) that if food metabolism is eliminated by twelve to fifteen hours' starvation (this means

the usual normal condition in the morning), and the metabolism of voluntary muscular effort is eliminated by absolute rest in a recumbent position (a half to one hour suffices), there remains only the energy output or heat production of metabolism of the circulatory and respiratory mechanism—a small and probably negligible addition for the phenomenon of secretions and entire chemical changes of the cells of the body while at rest—and this is called basal metabolism.

The basal metabolism is quite constant, not only in the same individuals, but in all individuals when calculated in proportion to the area of body surface, and the variation in health in a large majority of people probably is less than 10 per cent. from the average rate. The clinical estimation of this basal metabolism, therefore, is a very practical and reliable guide; but while comparatively easy, it requires the utmost care and accuracy.

Before making any final decision as to the functional state of the thyroid gland, clinical metabolism should be done; first having eliminated such other causal conditions, aside from variation in thyroid function, which may produce fluctuations of the basal metabolism, such as fever, severe cardiorenal disease, pernicious anemia, and, of course, age. These factors are all discussed in detail in the various papers on this subject and cannot be given more extensive consideration here.

As this method becomes less complex and the apparatus more convenient, the application of metabolism study will greatly facilitate the development of accurate knowledge in regard to the factors underlying hyperthyroidism, and eventually information will be at hand enabling us to determine the cause of certain variations in pulse, cardiac activity, and other manifestations which might be due to coincidental cardiac or renal disease, and will also serve to modify our conception of conditions as, for example, in the instance where patients suffer from auricular fibrillation with hyperthyroidism, where the low pulse-rate might give a wrong impression, whereas, the metabolism remains high, no matter what the actual cardiac condition might be. In other instances, as recently reported by Sturgis and Tompkins of Boston, emphasis is laid on this aspect of the advantage of comparing basal metabolism with the pulse-rate in cases with hyperthyroidism. They call attention to the point that in other instances low pulse might be accounted for by the fact that these patients had a normal metabolism and their pulse-rate was unusually slow, when, in reality, the metabolism was much higher than normal.

It should be clear, however, that metabolism study is but a part of the investigation of these cases, and as Hoover puts it: "The diagnosis of Graves' disease should be made quite apart from studies in basal metabolism. If the diagnosis is once made, then the study of the patient's metabolism may be of some value in criticizing his progress. It will give some indication as to whether the patient is growing worse or improving. It is, however, by no means necessary, for the size of the heart and the heart-rate are far more dependable in estimating the progress of the disease than any guidance that basal metabolism may give. It is our practice at Lakeside Hospital (Cleveland)

to study the basal metabolism in all cases of Graves' disease and all suspected cases, but the measure is not really a diagnostic aid, and is not essential for guidance and criticism of the progress of the disease. Physicians in private practice who have no such laboratory facilities available are just as well situated as are clinicians who have well-organized laboratories at their disposal.

"The writer does not wish to imply by this statement that the study of metabolism in Graves' disease has been of no value. It has been of very decided value in contributing to the study of the subject, but research and practice are very different, and I am sure the writer is justified in making the statement that the clinician who requires a study of basal metabolism to make a diagnosis of Graves' disease, or who requires the basal metabolism for guidance in the criticism of the progress of his patients, must find himself in a very weak position, both for diagnosis and for treatment of the disease."

Laboratory Contagion of Malta Fever.—Meyer reports a case of this accident, but fails to state the point of entry. The incubation period was very long—six weeks—and the course showed six separate attacks of fever with afebrile intervals. The symptoms were notably attenuated.—*La Presse Médicale*.

DIAGNOSIS IN TUBERCULOSIS.

By OWEN PAGET, M.D.

PERTH, WESTERN AUSTRALIA.

In previous contributions to the *MEDICAL RECORD* I have described the simplicity of the treatment of tuberculosis by insufflation. Though this has been successfully employed by medical friends as well as myself, during the last three years, it seems as if its value has not yet been sufficiently appreciated by the profession at large.

Now though a treatment which claims a large percentage of recoveries and definite improvement in practically all cases will of itself inspire a spirit of scepticism and even opposition in such a hackneyed subject as tuberculosis, I yet think that many misapprehensions are due to the general want of knowledge by our profession of this disease. And this can hardly be wondered at, for with increased study, the more numerous appear to be the variations of the disease. So much so that latterly I have come to the conclusion that if there are thirty million cases of tuberculosis in the world, there are also thirty million types of the disease. Cases of tuberculosis differ much in the same way that faces are distinct from one another.

Under such circumstances at first sight the clinical study of the disease appears hopeless, and many, even experts, are seemingly oppressed by apparent difficulties. Yet this need not be if main facts established by authorities in various countries are fully recognized.

The incidence of tuberculosis in communities with established health bureaux is estimated at 90 to 98 per cent. of the population, and hospital records show that there are definite tuberculous lesions in 80 per cent. of post-mortems.

These figures demonstrate that practically everyone is attacked with tuberculosis in the same way that most people suffer from measles. It differs, however, from measles in that an attack, if recovered from, apparently confers no immunity; and only most careful investigation enables us to speculate as to whether recovery has taken place or not. Tuberculosis, unlike measles, is chronic in character, not usually resolving by crisis or with the appearance of a rash. Further, it is usually subacute in type.

Analogy certainly assists in understanding the ill-defined; and perhaps some of the characteristics of tuberculosis can justly be compared to certain diseases of the skin. For instance, a patient may suffer from a chronic patch of eczema almost all his life with little disablement or inconvenience. He may be subject to periodical outbreaks of psoriasis with much or little discomfort. An acute attack of eczema may disappear in a few days or become chronic. Some skin lesions leave permanent scars. A minute abscess of the skin may lead to pyemia and death.

The morbid anatomy of tuberculosis discloses itself as the lightest evanescent catarrh of a day or two duration on tonsil, pharynx, or bronchial tube, down to the gravest ulceration of tissue, whether lung, bone, or skin; and can even be pyemic in character as in miliary tuberculosis.

But the greatest of all difficulties seems to be the diagnosis of this disease. Academically it is pos-

sible that 50 per cent. of the world's population is suffering from tuberculosis. The practical test, however, is the finding of the bacillus in the sputum or lesion. As this test, though possibly effective in 70 per cent. of severe cases, at best demonstrates only 30 per cent. of all cases, it is exceedingly difficult to establish a criterion of who has or who has not tuberculosis.

Treatment by insufflation is a most effective diagnostic agent, but until this is more extensively employed its value cannot be adequately appreciated. And in order to stir our profession into some enthusiasm for the treatment of tuberculosis, it is necessary to establish some definite clinical manifestation of the disease.

The preponderance of tuberculous infection is in the lungs, and I wish here to restate the formula of that great clinician Dr. Samuel Gee, who taught that "*A pulmonary lesion which does not clear up in six weeks is either tuberculosis or empyema.*" There are, of course, obvious exceptions to such a law. But such rarities as malignant disease, hydatids, pulmonary aspergillosis, the edema of Bright's and cardiac disease, and syphilis hardly influence the main proposition more than one per cent.

For my part I regard any intestinal catarrh of over six weeks' duration as likely to be tuberculous, and have successfully tested chronic dysentery with insufflation.

The main objections to Dr. Gee's proposition which may be cited are pneumokoniosis or the dust phthisis of miners and stone cutters, and the chronic bronchial catarrh of colder climates, as it occurs in the poorer districts of big cities like London and Manchester.

As to the former, writing with a fair experience, I believe that miner's phthisis of any really serious degree is in all cases a tuberculosis engrafted on an irritated lung. And though I have no real acquaintance with the treatment of chronic bronchitis in cold climates, my experience with the analogous conditions here is that it is always tuberculous, and always satisfactorily responds to treatment by insufflation.

A nasopharyngeal or pulmonary catarrh which does not clear up in six weeks should therefore be regarded as tuberculous except, of course, empyema of sinuses or lung.

The probabilities of any chronic affection in any part of the body are that it is (1) tuberculosis, (2) syphilitic, (3) malignant. As some improvement may be expected in two or three weeks in any tuberculous lesion treated by insufflation, this may be employed as a useful diagnostic agent.

A method useful in practice, namely that patients take their temperatures four times daily, shows that large numbers of people, who apparently are quite well and able to carry on their work, both manual and clerical, are suffering from tuberculosis. This is a simple plan for the physician to keep in touch with his patient and for the patient to gauge his own condition of health accurately.

The necessity for a definite diagnosis in tuberculosis is most apparent when a remedy is brought forward. I have seen a case which had been treated for tuberculous laryngitis and aphonia for over a year in a special military hospital apparently cured by psychotherapy in a couple of hours; and hemop-

tysis much benefited by many hours' immersion in the sea in consequence of a transport being torpedoed. Yet experience tells us that neither psychotherapy nor immersion is likely to be of value in every case.

The vagaries of natural improvement and recovery in tuberculosis are so multitudinous as to lead to the assumption that a remedy to be of value must be potent with the patient "in extremis." This is farcical. Antidiphtheritic serum if used only on the tenth day would not be able to prove itself the invaluable remedy we know it to be.

Assuming that pulmonary catarrh, if of more than six weeks' duration, is tuberculous, then with any remedy all cases both with bacilli in the sputum and without must show, with a proper remedy, positive and definite improvement. The rate of recovery in the first and second stages should be practically 100 per cent. A series of cases should not be less than 500 in number; my own under military conditions was rather more.

Inasmuch, however, as clinical experts lay great stress on results in third stage cases, I will quote the experience of my friend Dr. Birmingham in these cases in general practice (over a period of rather more than two years): "Of the third stage, four are dead, four have recovered, and eight are under treatment. Of these latter four have improved considerably, and are, I think, going to recover; the other four show a certain amount of improvement. By the word 'recovered' is meant that the disease had ceased to be manifest."

The incidence of tuberculosis is probably universal and the death rate is high. In its chronic disablements, however, are its devastating effects most widely shown. The number of people, especially in a country like England, who go through life with a diminished efficiency, ranging from 10 to 75 per cent., is appalling.

The early diagnosis of pulmonary catarrh as tuberculous, however distasteful it may be to the academicians, will I hope stimulate the profession to attempt its treatment by insufflations. The fact that so many recover by chance, or with the employment of empirical remedies, need not diminish the desire for the application of science in the treatment of this disease.

A CONCEPT OF X-RAY PATHOLOGY.

XIV. NEPHROPATHY.

BY A. J. PACINI, M.D.,

WASHINGTON, D. C.

CHIEF OF X-RAY AND LABORATORY SECTION, HOSPITAL DIVISION,
U. S. PUBLIC HEALTH SERVICE.

(Concluded.)

Renal Calculi.—The x-ray study in the question of renal calculus is, fortunately, more satisfactory than that for gall-bladder stones. It is generally agreed that an x-ray plate showing *Leonard's* criteria, clearly revealing the soft tissues in the renal region, will show the radiopacity of a urinary stone of any clinically appreciable dimension. The visualization of a kidney stone depends upon a number of factors, preeminently among which, as has been indicated, is the proper technology in the production of the plate. Another group of factors center about the composition of the stone in addition to which the density and size are also of consequence. Thus the composition of the calculus, its structure and its dimensions contribute to the probability of its x-ray demonstration. Renal calculi, for purposes of x-ray investigation, are divisible into five groups on the score of their chemical composition.

1. Uric acid stones. These are the least radiable and when small are the most difficult to demonstrate by means of the x-ray.

2. Urate stones. The composition of urate stones is variable as the basic metallic grouping may be essentially ammonium, calcium, sodium, or potassium. The radiopacity of urate stones, their size and structure being the same, is possible in direct relation to the atomic weight; so that ammonium urate stones are the least radiable, sodium urate more radiopaque, and calcium and potassium urate most radiopaque.

3. Oxalate stones. Oxalate stones are generally visible on the x-ray plate owing to their calcium content and because they frequently attain great dimension.

4. Phosphate stones. In these the base is almost entirely calcium or it may be double as calcium magnesium or ammonium and magnesium. In general, they cast definitely radiopaque shadows.

5. Carbonate stones. Here the base is calcium, or magnesium, or both. They are definitely radiopaque.

6. Miscellaneous group. Occasionally stones may form of a composition other than that just described, as for instance, cystine, xanthine, or other organic urinary constituent. Stones of these abnormal substances are uncommon, and when they do occur, it is seldom that the fundamental metabolic processes leading to their formation is so exaggeratedly perverted as to permit such stones to attain any great size.

On the topic of kidney stone structure it is only necessary to state that they may be simply homogeneous amorphous masses, or well-defined crystals,

or structures showing concentric laminations indicating their growth by successive accretion of layers.

The dimension of the stone is most variable. It may be barely visible upon naked eye inspection or it may attain the size of an egg, or even greater.

Speaking generally, a kidney stone uncomplicated by other factors and residing in the parenchyma of the organ, may present no clinical symptoms. It is only when in the pelvis of the kidney, or if in the pulp of the organ when complicated by associated infection, that the kidney stone is first suspected. So that we may speak of fixed or movable stones, meaning by the fixed those that lie embedded in the renal tissue, and by the movable those that are inclosed in an abscess cavity or lie free in the pelvis.

X-Ray Study of Renal Shadows.—In the event of a negative x-ray plate, by which is meant that an excellent x-ray visualization of the renal shadow and perirenal hard and soft structures are clearly and definitely demonstrable, it is wise to err on the side of conservatism and report the absence of any radiopacity suggesting a renal stone. Indeed, this form of report should be used by roentgenologists who venture an opinion on the interpretation of gall-bladder shadows with the view to diagnosing gallstones. An expression such as that just tendered is not one of ultraconservatism but rather a true statement of the limitation of the x-ray in its ability infallibly to detect the presence of stones.

Through the use of this expedient one will not report a negative finding without considering the possibility that there is present a stone too small to be visualized, or one composed of a radioparent matrix (uric acid cystine), both of which types, though the x-ray be negative, may give violently painful clinical symptoms.

When the x-ray negative shows a radiopaque area within the renal contours it is first necessary to exclude the possibility of foreign bodies or shadows due to other than stones. *Holmes and Ruggles* on the topic of shadows which may be confused with stones mention: (1) those due to material in the bowel, fecal masses, fruit pits, enteroliths, opaque salts, such as bismuth and barium (particularly residues in diverticulae of the colon), Bland's pills, salol capsules. The appendix often lies in close relation to the right ureter and foreign bodies or enteroliths within it may be mistaken for ureteral calculi. (2) Gallstones which can usually be differentiated by their structure and shifting position with reference to the kidney area on plates taken in the antero-posterior and postero-anterior diameters. (3) Calcified glands which have a spongy appearance usually sufficient to identify them. They occur along the course of the root of the mesentery, in a line from the left kidney to the anterior right sacroiliac, and in the neighborhood of the iliac vessels, differentiated by shifting position. (4) Tuberculous foci in the kidney may calcify and give shadows resembling those of stone. (5) Calcification in carcinomatous masses in the pancreas or glands may be a rare cause of confusion. (6) The tip of a transverse process may be so much more dense than the rest of it that it may suggest a stone. (7) Small areas of density in the spleen may overlie the upper portion of the

kidney. (8) Calcification in a blood clot or about a foreign body may simulate a stone if it overlies the kidney. (9) Mention must also be made of the shadows cast by fibromata, scars, and even dressings on the back which may be recorded on the plate as areas of increased density. (10) Artefacts in plates due to thin spots in the emulsion or small areas which are unequally developed may be a source of confusion.

Having excluded the question of artefacts one next studies the intensity of the radiopacity from which there may sometimes be gauged the composition of the stone. The number of the radiopacities is important as the stones may be multiple. The shape should be noted and the dimension, from which, if the stone is small and in the pelvis, the x -rayist may assist in producing its successful passage through the ureter. Then the location of the shadow must be ascertained and whether it is fixed or mobile. The mobility of the stone is determined by raying in several positions, using the technique similar to that employed for demonstration of a fluid level in a pulmonary abscess. The summary given by S. Gilbert Scott (*British Medical Journal*, September 11, 1920) in the study of renal shadows is excellent:

If a large dendritic calculus is present the diagnosis is easy, but at the same time the outline of the affected kidney will give additional data: (1) State of the kidney, such as the presence of hydronephrosis or pyonephrosis. (2) Its functioning powers as gauged by the thickness of the renal cortex; frequently the thinned wall functionless kidney can be seen moulded to the branches of a large calculus. (3) Fixation of the organ as shown by the absence of respiratory excursion which should be tested, as the surgeon will be grateful for any information on the subject of fixation if the kidney has to be removed.

Unless the abnormal shadow is that of a typical dendritic stone, some method should consistently be used to prove that it is in connection with the kidney. Appearances are very deceptive, and no matter how like a stone it may seem to be on the plate, guesses backed by experience should be replaced by a more scientific and accurate method. I have made it a rule for several years before giving an opinion on any abnormal shadow appearing inside the borders of the renal outline that it must be proved to be connected with or outside the kidney itself. This has saved me many a wrong conclusion.

The method may be summarized as follows: (1) The outline of the kidney must be seen. (2) An abnormal shadow lying outside this cannot be in the kidney. (3) If the shadow lies inside the limits of the outline, then it is necessary to compare the plate taken at full inspiration with one taken at full expiration.

The respiratory excursion of the kidney is first measured and the respiratory movements of the shadow under discussion are then compared. The direction of the movement of each is also noted. If the respiratory excursion and direction of the kidney and abnormal shadow are the same, the latter must be in connection with the kidney. A rule, therefore, can be formulated that if an abnormal shadow or shadows, no matter how small and insignificant they may be, lying inside the renal outline, move to the same extent and in the same direction as the kidney, they must be connected with it. This rule will apply to one or several shadows, and in this way it is quite easy to pick out from a number of shadows those that are of renal origin. In some cases the kidney may be fixed, and no respiratory excursion obtainable. If, however, it is possible to demonstrate that the shadow under discussion has moved in some direction or other, while the kidney has remained unaltered, the shadow must be outside the kidney.

Once having diagnosed the presence of a stone in the kidney, its correct position in the organ itself can be given, and a rough estimate made as to its size;

if the surgeon has confidence in his radiological colleague, he has only to make an incision into that part of the kidney in which the stone has been localized, just large enough to extract it with forceps, thus doing away with the somewhat drastic mutilation of the kidney which usually takes place when searching for stones.

This method of localization is invaluable where the shadow is extremely indefinite and doubt is felt as to its nature. These ill-defined "smudges," a term their appearances suggest, are very often the only evidence of tuberculous disease in a kidney; consequently it is of great importance that they should not be overlooked; having been detected, the diagnosis is clinched if they can be located in the kidney itself. An abnormal shadow, however insignificant, must not be ignored, but unless these shadows can be proved to be of renal origin, they are of themselves not of much value.

In order to make the method described clear, a few examples may be given:

1. A small single shadow is detected lying over the lower half of the kidney, say 20 mm., from the lower edge and 20 mm. from the outer edge. On comparing the inspiratory and expiratory plates it is found that the kidney and the shadow show the same respiratory excursion, say 30 mm., in a downward and outward direction, and the relation of the shadow to the kidney is unaltered. This proves that the opacity has moved with the kidney, both as to direction and extent, and is therefore of kidney origin.

2. The shadow is lying over the lower pole, but on comparing the inspiratory and expiratory plates it is found to have moved clear of the kidney altogether. This at once demonstrates that it is outside the kidney.

3. The same thing can be proved if the opacity is found to move downwards, say 10 mm., while the kidney shows an excursion of 20 mm.

These examples will suffice to illustrate how the method can be utilized. The comparative measurements are quickly made, and a small transparent meter rule will be found very useful for this purpose.

Ureteral Calculus.—Those factors that guide in arriving at the diagnosis of kidney stones are, of course, the ones used in arriving at a diagnosis of ureteral stones. There is only the additional question of the position. It cannot be too strongly emphasized that more frequent use of the cystoscope should be made in assisting in the diagnosis of kidney and ureteral stones. In cases of suspicious shadows that appear in the general course of the ureter, there should be passed a leaded catheter and every effort made definitely to establish that the radiopacity actually lies in the urinary tract. In a number of instances it has been personal experience to have passed a catheter and found that a shadow lay entirely without the ureter.

Bladder-stones are usually large and readily detected. It seems a very frequent error to call bladder-stones certain small sesamoids, perhaps two or three, that appear above the pubic arch on each side of the symphysis in practically every normal bladder plate. These should, of course, be cautiously avoided.

Pyelography.—In the study of the urinary tract made opaque by the use of certain injections, Braasch (*American Journal of Roentgenology*, December, 1920), presents a summary so complete and terse as to merit its quotation in full.

Voelcker and von Lichtenberg first demonstrated, in 1906, the feasibility of outlining the renal pelvis in the roentgenogram by injecting the pelvis with an opaque medium. The value of this method was not appreciated, however, until several years later, when American observers developed the method to its present scope, and subsequently it was widely adopted.

The procedure was first used to outline the pelvis, later the ureter, bladder, and urethra. With the in-

crease of the scope of the method, the original term of pyelogram became manifestly insufficient. As a term which will represent the roentgenographic demonstration of the entire urinary tract, I should like to suggest "urography." Such a term would not interfere with the retention of the accepted terms referring to the different areas, namely pyelography, ureterography, and cystography.

Urography entails unusual and highly specialized technical difficulties, and unless judiciously employed it is not without great danger to the patient. Its use should, therefore, be confined only to the experienced urologist and roentgenologist, working in close co-operation. Furthermore, it should be used only when the clinical diagnosis cannot be made without it. Urography is contraindicated (1) when the patient is in advanced age or greatly emaciated, (2) in cases of advanced bilateral renal disease, and (3) when it is apparent that surgical treatment will be of no benefit.

Extensive improvements have been made in recent years in the mediums employed in urography. The first medium suggested was a solution of colloidal silver termed "collargol." It was found, however, that the silver solutions were really not solutions, but suspensions, and that the undissolved silver particles acted as foreign bodies when injected into the kidney pelvis. Moreover, it was demonstrated that mediums injected into the renal pelvis frequently entered the tubules, the glomeruli, and the small capillaries. When the fine particles of silver became lodged in the tubules, they acted as foreign bodies and frequently caused infection. It is necessary, therefore, that mediums employed in urography should be true solutions and not suspensions. With this in view, Burns suggested a solution of thorium, which overcame many of the objections to colloidal silver and still remains an admirable medium. Unfortunately, solutions of thorium occasionally have toxic effects and are difficult and expensive to prepare. Shortly afterward solutions of the iodids were suggested by Cameron, and later Weld used the bromides. These two mediums are now the most widely employed. The ease with which the bromids and iodids are prepared and their cheapness, together with the excellence of the shadows they cast, make them desirable. They may be slightly irritating to the mucous membrane, however, particularly if they are retained in the renal pelvis. In spite of the fact that these solutions are comparatively harmless, it is necessary to employ great care in the technique of their application. The medium should usually be introduced into the pelvis by the gravity method; it may be injected with a syringe only by an experienced urologist. Every precaution should be taken not to cause pain on injection. As a rule 5 c.c. of the medium will suffice, and it is rarely necessary to employ more than 10 c.c.. After the x-ray exposure is completed, it is advisable to remove the injected medium as completely as possible, particularly if there is evidence of uretral obstruction. This may be accomplished by allowing the catheter to remain in the pelvis for some time and diluting with sterile water. Any medium, if allowed to remain in the renal pelvis, may be the cause of renal infection. It seems probable that this is the result of bacteria, which in spite of every precaution are introduced by the medium. Bromid and iodid solutions, however, may cause irritations even without infection when retained in the pelvis, and considerable reaction in the renal tissue. In case the retained medium causes renal infection, it may be advisable either to consider an immediate nephrectomy or to insert a uretral catheter into the pelvis and allow it to remain there. The formation of multiple cortical abscesses frequently noted in this condition is identical with septic nephritis and should be treated as such. Procrastination, in the hope that the acute process will subside, is of great danger to the patient, and it is seldom advisable to delay nephrectomy more than forty-eight to seventy-two hours after the first evidence of sepsis.

It is ten years since we began to employ urography in the diagnosis of disease conditions of the genito-urinary system, and it is appropriate that an inventory should be made of its practical value. The value of urography in selected cases of hydronephrosis, nephrolithiasis, pyelonephritis, neoplasm, and anomaly is unquestioned. It should be remembered also that the

demonstration of a normal pelvis may be of as much diagnostic value as the demonstration of one that is pathologic.

Hydronephrosis.—A diagnosis of dilatation of the renal pelvis as the result of marked mechanical obstruction should usually be made without the employment of pyelography. The presence of residual urine in the renal pelvis can usually be determined if more than 15 c.c. of urine can be withdrawn with a syringe through a uretral catheter or by the overdistention test; a pyelogram is then not necessary. If, however, the usual cystoscopic technique is insufficient to reveal the presence or absence of pelvic dilatation, pyelography may be an important measure. This is particularly true in cases of moderate pelvic dilatation, and in cases of impassable obstruction to the renal catheter. The interpretation of the pyelogram in cases of hydronephrosis may be very difficult, due to (1) impassable obstruction at the ureteropelvic juncture, (2) dilution of the medium by retaining fluid, and (3) insufficient medium injected to outline the dilated pelvis. It may be difficult to distinguish between hydronephrosis and neoplasm when there is unfavorable obstruction at the ureteropelvic juncture. Occasionally dilution of the injected medium by urine retained in the pelvis will cause scattered areas which suggest neoplasm.

Neoplasm.—Pyelography is recognized as a frequent valuable aid in the diagnosis of neoplasm. When a pyelogram is followed by a marked reaction, as with hydronephrosis, an immediate nephrectomy is advisable, since septic nephritis may complicate the neoplasm. Here, again, the method should not be employed as a routine procedure, but only if the diagnosis is not possible without it. The differential diagnosis of epithelioma of the renal pelvis and tumor in the renal cortex may be difficult. A hydronephrosis, together with the deformity usually seen with neoplasm, suggests pelvic epithelioma. The greatest difficulty has been to distinguish between neoplasm and polycystic kidney. The character of the deformity may be identical in both conditions. As a rule, however, they are distinguished by the fact that a neoplasm is characterized by the retraction and narrowing of the calices, while polycystic kidney frequently has an abbreviation of one or more of the calices, and seldom any narrowing. It should be remembered, however, that when polycystic kidney is apparent from the clinical examination pyelography should not be employed. Not infrequently the medium will not drain from the calices because of the obstruction caused by the dilated cysts, and cortical infection may ensue. Bilateral pyelography in cases of polycystic kidney is particularly contraindicated.

Nephrolithiasis.—The purpose of a pyelogram in cases of nephrolithiasis is to identify and localize the shadow. As a method of identification it is of considerable value, particularly in the differentiation of shadows on the right side which may easily be confused with gallstones. However, since the introduction of fluoroscopy at the time of operation localization of the stone is not of great value. Identification of shadows in the ureter by means of ureterography still remains the best method. The relation of a leaded catheter inserted in the ureter to a shadow in the ureteral area is too indefinite to be of accurate diagnostic value when the catheter is less than 1 cm. distant.

Anomaly.—Demonstration of pathologic complications, together with anomaly of the kidney and ureter by means of urography is a valuable aid in their diagnosis. It must be remembered, however, that retention of a medium in a single kidney may offer serious complications. The demonstration of an anomalous position of a kidney, or of a fused kidney, can frequently be accomplished simply by the introduction of a lead catheter.

Distinguishing simple inflammatory dilatation from dilatation of renal tuberculosis is occasionally of importance. The extent of renal destruction as a result of chronic infection may often be appraised only by the demonstration in the pyelogram of marked inflammatory dilatation and cortical necrosis.

Cystography.—The clinical value of demonstrating the outline of the bladder, which is termed cystography, as an aid to diagnosis, is not fully appreciated. It may be of considerable diagnostic aid in the presence

of vesical neoplasm, vesical diverticulum, and prostatic obstruction, particularly when a complete cystoscopic examination is impossible, because of excessive hematuria, intolerance, contraction of the vesical lumen, or impassable urethral obstruction. The existence of a vesical tumor may be inferred from the presence of a filling defect in the outline of the bladder. The extent and character of the filling defect may also determine the size and nature of the tumor. It must be remembered, however, that partial distention of the bladder, reflex spasm, presence of blood clots, and so forth, may cause error in interpretation.

Diverticulum.—The opening of a diverticulum of the bladder is very easily overlooked on cystoscopic examination, and the diagnosis may be possible only by means of a cystogram. In fact, even though the opening of a diverticulum is visible on cystoscopic examination, a cystogram is advisable because of the possibility of the presence of multiple diverticula. Since a cystogram taken at one angle may easily overlook the presence of a diverticulum, it is always advisable to make an exposure in the anteroposterior position, and at the right and left angles. This will render visible the outline of the diverticulum, which might otherwise be obscured by the overlying bladder. Further, it is advisable to have the patient empty the bladder as completely as possible, and repeat the cystogram. A lead catheter coiled in the diverticulum is sometimes of value in determining its size. Diverticula of the urethra and urethrocele may also be determined by this method.

Prostatic Obstruction.—Occasionally for technical reasons it may be difficult to make a cystoscopic examination in the presence of prostatic obstruction. A large prostatic gland, particularly with median intravesical projection, will cause a filling defect of the bladder outline at the urethral opening. Occasionally, however, such an evident filling defect may be caused by gas in the bowel, and failure to distend the bladder, and prostatic obstruction may be erroneously inferred.

Cysto-ureterogram.—A cysto-ureterogram may be of some value in certain cases, particularly if there is marked inflammatory dilatation of the renal pelvis and ureter, and if the cystoscopic examination is unsatisfactory. The cysto-ureterogram is made after the bladder is filled with an opaque medium while the patient is in extreme Trendelenburg position. If the lower ureter and meatus are patent the medium will gravitate into the dilated ureter and occasionally into the renal pelvis. The method, however, is not without danger if the medium enters both renal pelves and is then unable to drain readily.

In conclusion, it may be said that urography is one of the most valuable aids we have in the diagnosis of lesions involving the urinary tract. Its limited application, and the difficult and dangerous technique unless carefully safeguarded, will restrict its use, but the method merits a wider employment, and, I believe, in the future will receive it.

Medicolegal Notes.

Action Against Executors on Note by Patient for Physician's Fees.—In an action by a physician on a note for his fees brought against the executors of the deceased maker of the note, it was contended by the defendants that by reason of the proof that the note was executed by a patient to her physician during such relationship, the presumption arose that it was obtained by undue influence and without sufficient consideration, and that the burden then shifted to the plaintiff to prove that the transaction was voluntary and based upon an adequate consideration. It undoubtedly is the established rule that the relation of physician and patient is confidential, and the law demands the strictest good faith and fair dealing in all transactions arising from that relationship. Once this relation is shown to exist, all dealings between the parties will be closely scrutinized, to ascertain if the confidence of the trusting party has been betrayed, or his mind unduly influenced to his prejudice. But when satisfactory proof has been made that a person has freely and voluntarily disposed of his property in accordance with his wishes, and his capacity and volition are

apparent, the existence of the confidential relation will not prevent the consummation of his desires. Under the provisions of section 2235 of the California Civil Code, creating a presumption that transactions by which a trustee obtains any advantage from his beneficiary are without consideration and under undue influence, the mere fact that a confidential relationship existed between the parties is not sufficient to overcome the presumption of consideration evidenced by a writing under sections 1614 and 1615 of the Civil Code. It must be made to appear that the relationship was used to obtain an unfair advantage, or that the confidence was violated. *Dimond v. Sanderson*, 103 Cal. 97, 37 Pac. 189. The rule is less stringent where it appears that the trustee was not advising the beneficiary in the conduct of business, but assumes a hostile attitude, and is urging the payment of a debt due himself. It was pointed out by the court that the result of a drastic application of the rule invoked here would be to preclude a physician from bargaining with a patient in regard to his fees, and to deprive persons occupying confidential relations of the power of contracting with each other for compensation, which, in all cases, would of necessity be fixed by a court or jury regardless of the circumstances under which the parties arrived at an agreement between themselves. In such an action the physician's testimony as to the transaction is excluded by section 1880 of the California Code of Civil Procedure. Although it did not appear that the physician disclosed to his patient the amounts which he paid to his assistants or to other physicians, the evidence showed that the patient was in full possession of all her faculties, acting freely and voluntarily, with knowledge of all the doctor had done for her during her illness, and in appreciation of his services executed the note in payment of his account, believing it to be a reasonable charge. In the absence of undue influence the adequacy of the consideration was held to be immaterial. *Silveria v. Alexander*, 25 Cal. App. 506, 144 Pac. 303. A verdict for the plaintiff was therefore affirmed.—*Cole v. Wolfskill* (Cal. App.), 192 Pac. 549.

Physician Experienced in Treating Burns from Electricity May Give Opinion as to What Current Would Cause Death.—In an action for death from contact with electricity a physician was produced as a witness for the plaintiff. Having testified that he had had much experience in treating burns caused by electricity, and having, in answer to proper questions, detailed the peculiar character of such burns, and having further testified that as coroner he had examined the body of the deceased after death, he was permitted, over the defendant's objection, to testify that he found "electrical burns on the left breast" of the deceased, and that, in his opinion, the effect of a current of electricity sufficient to cause the said burns "would be death." It was held the trial court did not err in the admission of this evidence. The nature and character of the burns found, and the effect of an electrical current sufficient to produce them, were matters calling for expert knowledge, and the witness having qualified as an expert, his testimony as to such matters was properly admitted.—*Haskell et al., Co. v. Erickson* (Ind. App.), 128 N. E. 466.

Degree of Care Required in Treating with X-ray.—On a second appeal in an action for damages alleged to have been caused by the use of the x-ray in treating the plaintiff for a small spot of eczema about the size of a silver dollar, the Texas Court of Civil Appeals said that the rule in Texas to determine the liability of physicians or surgeons for injuries sustained from negligence in the use of x-rays is the same as in other classes of cases, in that the physician is required only to use such reasonable care and skill as is ordinarily exercised by reputable physicians in the locality. The physician is not expected to look for unexpected results from treatment of his patients, but is compelled to look for natural and probable results. He is not expected to anticipate results arising from peculiar characteristics and conditions of a patient, nor is he an insurer of unexpected results. So, while the treatment and character of the injury may be looked to as a circumstance, in the absence of testimony explaining, it may or may not be conclusive.—*Hamilton v. Harris*, Texas Court of Civil Appeals, 223 S. W. 533.

THE "RATING SCALE" AND THE DOCTOR.

IN November, 1917, so the story goes, the attention of the Surgeon General of the United States Army was directed to the fact that the psychological examination of officers in the United States Army indicated that the intellectual status of medical officers was less satisfactory than that of officers of the several other arms of the military service. This report was based upon observation of the psychological service and data of examination at Camp Lee, Virginia. Quite naturally this arraignment met with critical interest on the part of the medical profession. If one takes seriously the entire matter of psychological tests, intelligence ratings, and kindred ability measurements, even more interesting must be the report of the follow-up work, so to speak, conducted by the Division of Psychology of the Surgeon General's Office during 1917 and 1918, and now put forth by the National Research Council.* For, whereas the first preliminary report was based on examinations in only one camp, the present report deals with examinations conducted in a large number of camps, and involves about 15,000 records, some 3,000 of which were of medical officers. And—again if one takes the work quite seriously—additional interest must attach to the present report, since it may be taken to be in the nature of correction or confirmation of the preliminary report.

Summarizing their findings in the beginning, Cobb and Yerkes prepare the reader for the worst by plainly stating that the intelligence rating of medical officers is lower than that of members of the other arms of the service with the exception of the Dental and Veterinary Corps, while it is practically the same as that of the Quartermaster Corps. Nor do they long leave the civil practitioner to harbor delusion that this applies only to Regular Army medical officers. Indeed, they tell us that officers of the Regular Army Medical Corps and of the National Guard achieved somewhat higher intelligence ratings than did those of the Medical Reserve Corps. And no extenuating circumstance in the nature of professional obscurity on the part of the officers subjected to the tests is left to soothe

*Bulletin of the National Research Council, Vol. 1, Part 8, No. 8, 1921: Intellectual and Educational Status of the Medical Profession as Represented in the United States Army, by Margaret V. Cobb and Robert M. Yerkes.

the ruffled self-esteem of those who may be tempted to make comparisons in their own favor. For lo! "The typical medical officer of this group claims membership in two or three medical societies, one of which is usually the American Medical Association." Success, measured in terms of earnings, furthermore, fails to prove a pacifier, for "surprising as it may appear, earnings in the medical profession apparently are not dependent upon intelligence."

In seeking an explanation for these and the many other interesting findings of these psychological examinations, Cobb and Yerkes suggest, as chief among the factors responsible for the relatively low standing of medical officers, age, habits of deliberateness and accuracy developed by professional training and experience, characteristics of the tests which render them easier for engineers than for medical officers, and method of military selection.

To advocates of universal military training the last of these factors must seem significant. By far the larger part of the group had been commissioned in the Medical Officers Reserve Corps. There were included, however, small groups of officers of the National Guard and of the Regular Army. These two small groups made a much better showing on "examination alpha" than did the larger group from the Medical Officers Reserve Corps. The medical officers of the Regular Army, in fact, did as well as officers of any branch of the Army except the engineers. The small size of the group, however, makes the reliability of the median score uncertain. This score, we are told, is 143 for the National Guard and Regular Army combined, as compared with 128.6 for the Medical Reserve Corps.

"Examination alpha," it may be stated for the benefit of those who have neither fallen into the hands of the psychological examiner nor given special thought to the matter of mental tests in general, consisted of eight separate tests, the time limit on which was so short that very few men could finish a given test. These several tests are enumerated as: Test 1, oral directions; test 2, arithmetic; test 3, practical judgment; test 4, opposites; test 5, disarranged sentences; test 6, number series completion; test 7, analogies; test 8, information. The examination required approximately fifty minutes.

It is not within our province to pass judgment upon the value, from a military or civilian point of view, of these or any other tests as measures of ability to execute the business in hand. It is believed, however, that many a man who would make an inglorious rating in a psychological examination would render brilliant service when occasion demanded the utilization of his reserve capability, whether in commanding armies, building bridges, or treating physical infirmities.

THE TREATMENT OF SURGICAL TUBERCULOSIS IN CHILDREN BY VENOUS HYPEREMIA.

IN children the induction of venous hyperemia is not only quite equal to any other modern method of treatment of white swelling of the knee joint, with the exception of heliotherapy, but it is distinctly

superior in many respects. The rapid sedation of pain is one of the first results when the procedure is properly employed. The bad position assumed by the involved limb improves spontaneously as soon as the pain disappears. The possibility of carrying out the treatment without the use of casts or other means of immobilizing the limb avoids the development of trophic disturbances of the skin, muscles, and bone. Finally, when other therapeutic measures—always excepting heliotherapy—usually end in more or less complete ankylosis (which is even yet regarded as an ultimate aim), venous hyperemia, preserves the joints as well as their movement, and this is not uncommon, but almost invariably the rule. Therefore, it should be given a high place in infantile surgical therapeutics in which conservative measures are all-important. Added to these advantages treatment by venous hyperemia is absolutely inoffensive when rightly carried out.

The accidents attributed to it are invariably due to a defective technique. Muscular atrophy at the point of application of the elastic band, chronic edema and, exceptionally, gangrene have been recorded, but they are always the result of a too tight application of the band. Acute suppuration in the sinuses or in tuberculous abscesses may also ensue from the ischemia caused by a too tight ligature and tuberculous lesions appear to be particularly aggravated by this ischemia or by an exaggerated edema which produces a too intense or prolonged stasis. Consequently it is of utmost importance to watch for the slightest symptoms accruing from too energetic compression and to remedy this immediately. For this reason the simultaneous application of the elastic band and cups should always be avoided as they produce an excessive stasis over the bacillary lesion itself.

As to the manner of action of venous stasis one is reduced to hypotheses, each of which probably has a certain value, but no one taken singly is sufficient to give a satisfactory explanation. It must be admitted that the true *modus operandi* of the procedure still remains to be explained, but the numerous excellent—even exceptional—results plead in its favor. Its use is indicated at the onset of white swelling of almost any joint when the lesions are especially in the periarticular soft parts, and in osteitis with or without sinuses, when the bone lesion is superficial. Venous hyperemia can also be used to complete the results of a surgical interference on the bones. Like all other conservative measures this one is contraindicated in very advanced tuberculous lesions of the bones and in rapidly developing osteoarthritis, when it is urgent to prevent the occurrence of visceral degeneration by resorting at once to a radical operation.

FATAL HEMORRHAGE IN CANCER.

It is safe to state as a rule that cancer bleeding is not lethal and indeed seldom serious, but rarely it has been sufficient to cause a fatal issue. Such an accident is most apt to occur in gastric, rectal,

or uterine cancer. In an article on the subject in the *Revue médicale de la Suisse romande* for February, 1921, xli, 2, Koehlin does not mention the severe hemorrhages often seen in chorioepithelioma which is essentially hemorrhagic in character, but appears to refer to pure accident such as hemorrhage from ulceration into a large blood vessel. Cancer as such is almost always accompanied by microscopic hemorrhage believed to be due to defective formation of the capillaries. These minute hemorrhages are in fact responsible for the central necroses seen in cancer. Severe hemorrhage appears never to have been the consequence of an exaggeration of this phenomenon. Ribbert, Borst, Askanasy, and other authorities in fact deny or ignore the existence of severe primary hemorrhage in cancer. There only remain then secondary hemorrhages due to ulceration of arterial walls.

The cumulative incidence of rare accidents is well shown by the recent experience of the Geneva Surgical Clinic. The first case occurred in a man of 50, presumably healthy although bothered a little with constipation alternating with diarrhea. On one occasion he had a sudden call to stool and passed much pure blood. The hemorrhage recurred several times until he must have lost a gallon. Despite all aid he succumbed to progressive loss of blood and at autopsy the source was found to have been a non-stenosing cancer of the rectum which had ulcerated into the lumen of an artery. The diagnosis had already been made by the proctoscope.

The second case occurred in a patient with cancer of the lesser curvature in whom gastroenterostomy had already been performed. Death followed a fatal hemorrhage from erosion of an artery by the extension of the ulcer. The third case occurred in a man who had submitted to a resection of the pylorus for cancer. Death resulted from ulceration of the great curvature opening into the splenic artery, the cancer having recurred in that locality. The fourth patient succumbed to hemorrhage of the jejunal artery in connection with the invasion by a scirrhus of the pancreas of the duodenojejunal angle. In the fifth case the artery ulcerated was one of the coronaries of the stomach. A sixth case occurred in the clinic of Professor Buettner, the gynecologist. The neoplasm was seated in the cervix and had been improving under radium and the x-ray when death suddenly took place. The ulceration into the uterine artery might not have occurred had not the vessel been the seat of a small aneurysmal dilatation. The six cases all occurred during 1919-20.

INOCULATION OF MEASLES.

NUMEROUS attempts to inoculate monkeys with human measles have been made, but only recently has success followed the many negative early experiences. The disease has been conveyed from man to monkey, monkey to monkey, and on one occasion from man to man. Yet it must not be understood that through experience and improved technique the problem of inoculation has been finally solved. On

the contrary some of the positive experiments are old and some of the negative comparatively recent. In a review of the subject contributed by Bonnin to the *Gazette hebdomadaire des sciences médicales de Bordeaux*, for April 17, 1921, xlii, 16, it is stated that some experiments reported from Johns Hopkins in 1919 were negative, while Nicolle reported success as far back as 1911. But the positive results of Nicolle and Conseil in 1920 and of Blake and Trask in 1921 tend to show that investigators in different parts of the world are obtaining standardized results. Nicolle and Conseil injected into the veins of a healthy infant 8 c.c. of citrated blood from an infant ill of measles and nine days later classical measles appeared in the former. In the monkey the incubation period after intravenous injection was four days, and after intratracheal injection seven days. In the latter experiment the substance injected was obtained by lavage of the nasopharynx of measles subjects before and after the eruption had appeared. Hemoculture in these experimental cases has always proved negative. The laboratory disease was transmitted from animal to animal through six passages. From these experiments we have learned that a measles subject is pretty well saturated with the contagious principle which appears to exist in the mucous secretions of the upper air and food passages, the skin, blood, and tissues in general. Negative results of inoculation are evidently in part due to taking the inoculable material at too early a date after inoculation or natural contraction of the disease. This may not be used until the seventh or tenth day after the natural or artificial infection.

DOES NEOSALVARSAN SPLIT OFF THERAPEUTICALLY ACTIVE FORMALDEHYDE IN THE BODY?

AS far back as 1917 Grosz claimed that a cleavage of neosalvarsan took place in the kidneys, and he began to inject this substance intravenously in cases of pyelitis and pyelocystitis, claiming 80 per cent. of cures. The doses were unusually small—three only of 0.15 gm. each. Cases of catheter-cystitis also were specially suited for this treatment. The drug seemed, however, to be inert in colon bacillus infections. Sachs has recently tested both neosalvarsan and urotropin intravenously in this class of cases, but obtained more negative than positive results. (*Wiener klinische Wochenschrift*, April 14, 1921, xxxiv, 15.). He believed that urotropin splits off more formaldehyde than neosalvarsan, even dose for dose, to say nothing of the unlikelihood that such small doses of neosalvarsan could deliver enough of this substance to obtain its characteristic action. Yet Grosz asserts that he has repeatedly cured catheter-cystitis with a single injection of neosalvarsan. But when large doses of urotropin itself cannot attain this result, Sachs says, how can Grosz explain such successes by the meager amount of formaldehyde split off from neosalvarsan? The author then investigated the formaldehyde content of several drugs known to contain it. He ascertained that urotropin might split off as high as six molecules of formaldehyde. Paradoxically, but owing to regrouping of the water in the molecule, the formaldehyde derived from urotropin may weigh more than the dose of the latter given. But 0.15 gm. of neosalvarsan cannot split off more

than 0.006 gm. of formaldehyde. Grosz admits that old salvarsan is inert in pyelitis and does not split off formaldehyde. It can only be urged that whatever benefit there may be in neosalvarsan in these urinary affections it cannot be due to formaldehyde, or at most can be only partly due to that substance.

News of the Week.

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION.

(By Telegraph to the MEDICAL RECORD)

At the meeting of the House of Delegates on Thursday afternoon, the following officers were elected:

President, George E. de Schweinitz, Philadelphia, Pa.

Vice-President, Frank B. Wynn, Indianapolis, Ind.

Secretary, Alexander R. Craig, Chicago, Ill.

Treasurer, William Allen Pusey, Chicago, Ill.

Speaker of the House of Delegates, F. C. Warnhues, Grand Rapids, Mich.

Trustees, Frank Billings, Chicago; Wendell C. Phillips, New York; Thomas McDavitt, St. Paul, Minn.

The next annual session, in 1922, will be held in St. Louis.

Opposition to the Sheppard-Towner Bill.—The American Gynecological Society, at its Forty-sixth annual meeting held June 2-4, 1921, took the following action opposing the Bill for the Protection of Mothers and Infants, commonly known as the Sheppard-Towner Bill. This action of the Society was taken, almost unanimously, after careful consideration of a report of its Committee on Maternal Welfare, acting jointly with a similar Committee of the American Child Hygiene Association:

This Society wishes definitely to state its position for the information of the medical profession and others who are interested in this legislative program.

1. The committee is in thorough accord with the ends which this bill seeks to attain, namely, the protection of the health of mothers and infants.

2. We indorse the coordination of all health activities under one head. We consider the protection of mothers and infants to be a *health measure* of paramount importance to the individual and the State.

3. We oppose in principle the control of health measures by non-medical individuals or boards.

4. We believe in the local control of health activities as distinguished from federal. We approve and indorse the idea of propaganda and investigation emanating from the Federal Government.

5. We do not indorse the Sheppard-Towner Bill in its present form because it does not conform to the above principles and because it embodies the questionable plan of subsidizing State health activities.

6. We endorse the project of establishing a National Department of Health.

President, George Gray Ward, Jr.; *Secretary*, Arthur H. Curtis; *Committee*, George W. Kosmak, Fred J. Taussig, Fred L. Adair (Chairman).

New Public Health Service Hospitals.—Nine new hospitals of the U. S. Public Health Service which will accommodate more than 3,000 patients, are now being put into shape for early occupancy. The Colfax hotel, at Colfax, Iowa, a leased building with 130 acres of grounds, is being fitted to receive 200 patients. The Army hospital at Fort William Henry Harrison, near Helena, Mont., will be opened with 100 general patients, but may later be greatly expanded. The buildings at Dawson Springs, near Hopkinsville, Ky., call for extensive repairs, but the

hospital will probably be opened with 500 tuberculosis patients within five months. The Hahnemann hospital at Portland, Ore., should be ready for 164 general patients by July 1, and the Speedway hospital at Chicago for 1000 general patients by August 1. Of the three army posts specifically turned over by Congress, that at Fort Walla Walla has been abandoned for a year and, except for two brick barracks, its buildings are in bad condition and must be rebuilt. It will shelter 284 tuberculosis patients. Fort McKenzie, one mile northwest of Sheridan, Wyo., is pleasantly situated against a northern shield of mountains. The red brick buildings of Fort Logan H. Roots, near Little Rock, Ark., stand on a bluff overlooking the Arkansas River. Forts McKenzie and Roots are each planned to accommodate more than 600 nervous and mental cases. Each of the three posts is likely to be ready in less than six months. A naval station at Gulfport, Miss., has just been taken over from the navy by the Public Health Service and will be utilized as a hospital or home either by the service or by some other branch of the government.

Male Immunity to Typhoid Fever.—The curious observation has been made in Paris that the typhoid fever cases are confined almost exclusively to girls and women, the only male cases being in young lads and a few quite old men. The explanation of this is that most of the men in the city have been in the army, where they were vaccinated against the disease.

Quarantine Appropriation Cut.—The Appropriation Committee of the House of Representatives has cut out the item in the deficiency bill setting aside \$287,620 for the improvement of the Quarantine Station at Baltimore. The committee also disallowed an appropriation for needed improvements at the Quarantine Station in New York.

Increase in State Aid to Hospitals.—In the Budget Bill before the Connecticut State Legislature increase is recommended aggregating \$177,800 in State grants to hospitals over the amounts allowed two years ago.

An Externship in Radiology.—There has been established at the Mount Sinai Hospital, New York City, a system of externship in the x-ray department. There are to be externes, each serving one year, one beginning February 1 and the other August 1. The next appointment will date from August 1, 1921.

Eugenics Law in Wyoming.—Under the terms of a law now in force in Wyoming every male person securing a marriage license must produce a certificate, dated within ten days and signed by a licensed Wyoming physician, showing the applicant to be free from venereal disease in a communicable stage.

Lackawanna County Medical Society to Build a Home.—A plan is under consideration by a committee of the Lackawanna County (Penn.) Medical Society to purchase or construct a building to accommodate its growing library and to provide a meeting place. The society numbers 200 members and the attendance at its weekly meetings is always large.

Protests Against Dr. Schley's Removal.—Dr. William C. Schley, a war veteran, wounded in action with the 102d Infantry, has been removed from

the staff of the U. S. Public Health Service Hospital in Boston, and the action has called forth vigorous protests from officers and members of the Massachusetts State Legion which asserts that Dr. Schley has accomplished more for disabled veterans asking medical aid and compensation than any other doctor in government service in the State.

Diphtheria Immunity in North Carolina.—The State Board of Health of North Carolina announces that diphtheria toxin-antitoxin will be supplied to all physicians in the State at the nominal charge of ten cents for the series of three doses.

Antirabic Virus in Maryland.—The Department of Health of Maryland has arranged for a more simple method of administering the virus used in cases of rabies. The department has advised physicians throughout the State that antirabic vaccine, in convenient form, is now purchasable at several drug establishments and that it can be employed by the local physicians—a method which is recommended.

Flying to Render Medical Aid.—Word was received by telephone one day recently at the Norfolk naval base that a coast guardsman at Manteo was ill and the only physician along the shore between Virginia Beach and Cape Hatteras could not be reached. Lieutenant C. L. Haines, M. C., U. S. N., was therefore sent in a seaplane to the place designated and rendered the necessary assistance.

An Army Medical Field Service School has been opened at Carlisle, Pa., under the command of Colonel P. M. Ashburn, M. C., U. S. A. It is expected that medical reserve officers and also medical officers in the various State militia services, as well as students in the Army Medical School at Washington will receive instruction at the field service school.

Graduation Exercises at the Army Medical School.—Diplomas were presented to 64 army officers at the closing exercises of the Army Medical School in Washington on May 26. The diplomas were awarded by Secretary of War Weeks. Music was furnished by the Marine Band. Surgeon General Merritte W. Ireland presented the Hoff Memorial medal to Major Albro L. Parsons. The Slee medal was presented to Captain Phillip P. Green by Colonel Richard Slee, and the Sternberg medal was awarded to Captain Virgil H. Cornell, the presentation being by Brigadier General Walter D. McCaw.

A Testimonial to Medical Veterans.—Commissioned medical officers of Harrisburg, Penn., and vicinity who served during the World War were entertained at a testimonial and dinner given on May 30 jointly by the Harrisburg Academy of Medicine and the Dauphin County Medical Society. Plans are being made to compile a history of the services of these medical men in the war. There were 43 men in active service, 17 served on draft boards and 14 on the medical advisory board.

Women Graduates at the Columbia P. and S.—In the graduation class of the College of Physicians and Surgeons of Columbia University, New York, last week were six women, the first of their sex to receive medical degrees from the university.

Dr. David Bovaird of New York City announces his withdrawal from practice here to become physician in chief of the Clifton Springs Sanitarium

at Clifton Springs, N. Y.

Dr. R. T. Miller has resigned from the medical faculty of the University of Pittsburgh. He was for twelve years connected with the department of surgery and since 1915 has been the head of that department.

Dr. E. E. Montgomery has resigned from the chair of gynecology at the Jefferson Medical College, Philadelphia, and Dr. Brooke M. Anspach has been elected his successor.

Dr. A. S. Pinto has been appointed health commissioner of Omaha in succession to Dr. J. F. Edwards, resigned.

Miss Anna C. Maxwell, since 1891 supervisor of nurses and director of the nursing school of the Presbyterian Hospital in New York City, will retire on June 30. Miss Maxwell has been in active nursing service since 1876.

Restriction on Medical Practice by the New Volstead Law.—The House Judiciary Committee has reported favorably on the new Volstead bill. The section of this bill affecting medical practice reads as follows: "No physician shall prescribe nor shall any person sell or furnish on any prescription any vinous liquor that contains more than 24 per centum of alcohol by volume, nor shall any one prescribe or sell or furnish on any prescription more than one-fourth of one gallon of vinous or any liquor that contains more than one-half pint of alcohol for use by any person within any period of ten days. No physician shall be furnished with more than one hundred prescription blanks for use in any period of ninety days, nor shall any physician issue more than that number of prescriptions within any such period unless on application therefor he shall make it clearly apparent to the commissioner that for some extraordinary reason a larger number is necessary, whereupon the necessary additional blanks may be furnished him."

Protests Against the Volstead Act.—At the annual meeting of the American Therapeutic Society in Washington last week resolutions were passed protesting against the restrictions of the Volstead Act on the prescription of alcohol by the medical profession. At the same time appeared a letter in the *Journal of the American Medical Association* signed by eight physicians of high standing in New York City calling attention to the intolerable restrictions placed upon the practice of medicine by the Volstead Act. The signers of this letter were Drs. Charles L. Dana, Samuel Lambert, Robert A. Hatcher, Hermann M. Biggs, Harlow Brooks, George B. Wallace, Walter N. James, and Warren Coleman.

Wireless for Doctors.—A portable wireless telephone set, costing only about \$50, which can be attached to any closed automobile, is said to have been invented recently in Cincinnati. It has a radius of five miles. Power is supplied by the regular storage batteries in the car, and the set is grounded to the engine. A physician in a car equipped with this apparatus can be notified of urgent calls while on his rounds, and can answer them promptly before returning to his office.

The Late Dr. Pisek.—The following resolutions were passed at a meeting of the Alumni Association of the University and Bellevue Hospital Medical College, held June 3, 1921: *Whereas*, In the death

of Godfrey Roger Pisek, the New York University and Bellevue Hospital Medical College Alumni Association has suffered the loss of its first treasurer, and the American medical profession and the New York medical fraternity in particular have lost a most distinguished physician, teacher, and specialist in the diseases of children; and *Whereas*, This Association is indebted to the late Dr. Pisek for having been one of the prime movers in its formation and in no small measure responsible for its success from the very beginning, and for his unabated interest until his untimely death; and *Whereas*, By his devotion to high ideals, his love for humanity and especially for the sick children of the poor, his skill as a teacher and diagnostician, he had endeared himself to his pupils and patients alike; and *Whereas*, Dr. Pisek, by his loveable personality, genial spirit, friendship for his colleagues and comrades, had endeared himself to all of us; be it

Resolved, That the Association records these tributes with the full consciousness of the profound debt it owes to the memory of Godfrey Roger Pisek and with a deep appreciation of his interest in our Alumni Association. And be it further *Resolved*, That these resolutions be spread on the minutes of this meeting, and be engrossed and transmitted to Mrs. Pisek and her daughters with the expression of profound sympathy in the great sorrow which has befallen them in the passing away of their distinguished husband and father; and be it further *Resolved*, That copies of these resolutions be sent to the medical press.

President of the Association: R. J. Carlisle. On behalf of the Committee on Resolutions: W. J. Pulley, Chairman; S. Adolphus Knopf, Secretary.

Obituary Notes.—Dr. FRANK AUGUSTUS BRYANT of White Plains, N. Y., a graduate of the Bellevue Hospital Medical College in 1895, died of pneumonia at the age of 69 years in the White Plains Hospital. Dr. Bryant was for many years conducting the Bryant School for Stammering, and was also engaged in active practice in New York City. For the past two years he was resident physician to the Burke Foundation at White Plains, N. Y. He was a member of the Westchester County Medical Society, of the Medical Society of the State of New York, of the American Medical Association, and of the New York Academy of Medicine.

Dr. FRANK H. EVERETT of Bradford, Pa., a graduate of Hahnemann Medical College, Philadelphia, in 1900, died on May 5, at the age of 70 years.

Dr. JOHN T. ALLEN of Brownsville, Tenn., a graduate of Bellevue Hospital Medical College in 1880, died of diabetes on May 9, at the age of sixty-four years.

Dr. STEPHEN THOMAS ROBINSON of Edwardsville, Ill., a graduate of Vanderbilt University, Louisville, Ky., in 1881, died of diabetes on May 4, at the age of sixty-two years.

Dr. JOHN N. LOVELL of Bradford, Ark., a graduate of the Memphis Hospital Medical College in 1895, died on May 12, at the age of fifty-three years.

Dr. DANIEL EDWARD ESTERLY of Topeka, Kan., a graduate of the University of Pennsylvania, Philadelphia, in 1893, died on May 8, at the age of fifty-four years. He was a member of the American

Academy of Ophthalmology and Oto-Laryngology and of the American Medical Association.

Dr. RICHARD BURGESS GILBERT of Louisville, Ky., died at his home on May 8, at the age of seventy-eight years. He was graduated from the University of Louisville in 1868, and for twenty-five years was a member of the faculty of his alma mater.

Dr. DANIEL GREENLEE CALDWELL of Concord, N. C., a graduate of the University of Maryland School of Medicine in 1885, died after a lingering illness on May 13, at the age of fifty-nine years.

Obituary.

SIMON BARUCH, M.D., PH.D., LL.D.

NEW YORK.

Dr. SIMON BARUCH, for forty years one of New York's best known physicians, died at his home in this city on June 3, after an illness of some weeks. He was born in Germany July 29, 1840, and came to this country to study medicine, taking his degree from the Medical College of Virginia in 1862. He entered the medical department of the Confederate Army, serving under General Robert E. Lee from 1862 to 1865. He was captured by the Union troops but was promptly exchanged as both the opposing armies were short of medical officers. After the war he settled in Camden, S. C., where he practised until 1881, when he moved to New York. He was elected president of the South Carolina Medical Society in 1874 and served as chairman of the South Carolina State Board of Health in 1880.

Upon coming to New York Dr. Baruch first engaged in general practice, being on the staff of the Northeastern Dispensary, and later became chief of the medical staff of the Montefiore Home. While there he became interested in the treatment of chronic disease by mechanical and non-medicinal means, and especially by hydrotherapy, a branch of the healing art which he was mainly instrumental in developing to a high degree. For years he urged upon the authorities the establishment of free public baths, but his voice was as of one crying in the wilderness. Nevertheless, in spite of opposition and ridicule, he persevered and finally succeeded in persuading the State Legislature to pass a law making obligatory upon all cities of 50,000 or more population the establishment and maintenance of free baths. The first free public bath was opened in Rivington Street in 1901, and in 1917, by order of the Board of Aldermen this bath was officially named "The Dr. Simon Baruch Public Bath." Chicago anticipated New York by naming one of her public baths after Dr. Baruch in 1910. In 1913 a hospital was built in his honor in Camden, S. C.

Dr. Baruch was professor of hydrotherapy in the medical department of Columbia University, New York, and was the author of "The Principles and Practice of Hydrotherapy," a work which passed through several editions and was translated into French and German. He was a member of the New York Academy of Medicine. He was president of the American Association for Promoting Hygiene and Public Baths, which held its annual meeting in Brookline, Mass., on May 10 and 11. This was at the time of the beginning of Dr. Baruch's final illness, but he wrote an address on his sick-bed and sent it to the meeting.

Correspondence.

OUR LONDON LETTER.

(From Our Own Correspondent.)

LONDON, May 24, 1921.

The Beating of the Heart.—Dr. E. H. Starling, professor of physiology at the University of London, gave a lecture on the evening of May 20, last, on the beating of the heart, or rather the title was "The Law of the Heart," and the action of the heart was revealed by the cinematograph. In the course of his lecture Professor Starling said there was no doubt that the heart was under the control of the nervous system, so that its action could be altered, increased, or diminished by the brain in accordance with the needs of economy. But in the heart they found a wonderful power of adaptation to the varying needs of the organism, a power which was quite independent of the nervous system. It had long been known that the heart of the mammal would beat for some minutes after being cut out of the body, and if they took pains to insure that the muscles constituting the walls of the heart continued to receive their supply of oxygenated blood, it could be made to beat for eight or twelve hours after the death of the animal from which it had been taken. However, the lecturer reminded his audience that what had been described and shown by means of the cinema was the action of the isolated heart. In the natural body the mechanisms were fenced round, protected and aided by the complex activity of the central nervous system, which was always acting on the heart, on its rate, and on its strength of contraction, and balancing its activity against that of the blood vessels, and co-ordinating it with the events which were occurring in every other part of the body.

Blood Tests for Workers.—Industrial medicine is coming to the front more and more, and this branch of medicine is largely preventive. To safeguard as far as possible the lives of the workers by protecting them against the perils of their various callings is a main object of preventive medicine. For instance, those engaged in industrial pursuits in which they are liable to contract poisoning may, according to Sir Kenneth Goadley, be subjected to blood tests which will show the degree of susceptibility to particular poisons to which they are prone. Sir Kenneth has for many years been making experiments in this direction and has also had a long experience as specialist medical referee in cases of industrial poisoning. Consequently, he has arrived at certain very definite conclusions which may be of the greatest value to industry, and these he has embodied in a lecture he will give soon before the Royal Society of Arts, when Mr. J. R. Clynes, the well-known labor M. P., will preside. Sir Kenneth, as a result of the experience he has gathered, holds the view that, whereas some workers are especially liable to poisoning, others are almost immune. By excluding the former class from employment in certain industries and employing the latter, combined with the strict observance of the rules in force for dangerous trades, it may be possible to effect drastic reductions in industrial sickness. Moreover, the worker should also be

tested for blood pressure. In the case of painters this procedure is particularly necessary as a body, these workers being liable to over-pressure of blood as a result of the use of turpentine in their trade. It may be pointed out that poisoning can be effected in more occupations and industries by far than is generally realized. It seems to have been shown that those engaged in the peat industry, for example, are liable to an irritation of the skin, which in predisposed individuals may be the exciting cause of cancer. Those who handle tar and pitch run a similar risk. Chimney sweeps are prone, it is said, to cancer of the scrotum. Makers of felt hats are liable to poisoning from the mercury employed in the manufacture. In the confectionery trade the workers suffer from an irritation of the hands owing to dabbling in sugar. During the war the shell workers who were employed on the capstan lathes came out in boils from contact with the lubricating fluid used to cool the tools. There are many other trades which are dangerous from a similar point of view and which, Sir Kenneth Goadley thinks, can be rendered very much less harmful. He argues that it is no hardship that a man should be told that he cannot work in a certain factory for which blood tests prove him to be unsuited. Selections are made of people who are mentally fitted for certain posts. An engine-driver is tested for color-blindness before he is allowed to drive an engine. Why, then, should not the industrial worker, in occupations liable to cause poisoning, be first tested to find out if he belongs to the class who are peculiarly susceptible to poisons?

Economy in the Administration of the Ministry of Health.—The manner in which the Ministry of Health has been adversely criticized in certain of the daily journals has resulted in the issue of an "economy" circular. This circular has undoubtedly been sent out by the Ministry under the most severe political pressure, mainly brought about by the molding of public opinion by journals which have made a target of the Ministry of Health in order to discredit the government. The claim that the Ministry of Health was one of the most extravagant of the governmental departments is not by any means borne out by facts. The amount expended on public health is but a small fraction of the total public expenditure, and, on the whole, satisfactory results are being obtained. Good health, after all, is the greatest asset of a country, and so much reform is needed in Great Britain to effect improvement in this direction that such efforts must necessarily cost a good deal of money. The direct outcome of the "economy" circular will be to impede, or rather to arrest, progress so far as projects for the betterment of health are concerned and will in many cases be the direct cause of decreasing the amount of health work done by many councils all over the country.

Endowment by the Rockefeller Foundation of Training College for Nurses in Brussels.—It has been announced recently that the Rockefeller Foundation has endowed a training college for nurses in Brussels in memory of Nurse Edith Cavell and Madame Depage. It will be remem-

bered that Nurse Cavell was shot by the Germans in Brussels on Oct. 12, 1915. Madame Depage was well known in New York, where she came with her husband, Professor Depage, for the meeting of the International Surgical Society, which was held in New York in 1913. Madame Depage was drowned when the Germans torpedoed the *Lusitania* on May 7, 1915.

Statistics of Leeds General Infirmary.—Leeds Infirmary is one of the most celebrated in the Kingdom and has always had the good fortune to have on its staff exceptionally able men, especially, perhaps, surgeons. Among those who have shed lustre on the name of Leeds are Sir Clifford Allbutt, who, by the way, is a physician; Sir Mayo Robson, and Sir Berkeley Moynihan, of course, both surgeons. According to the *British Medical Journal*, May 21 last, in anticipation of the annual meeting of the infirmary, which is usually held in March, but which this year has been postponed to May 25, the usual statistical tables of the numbers of patients attended to in the various departments during the year 1920 have been issued. The total number of patients treated within the walls of the infirmary as inpatients was 9480, practically the same as during 1919. Of the new patients admitted 3914 were men, 3347 were women, and 1500 children. The average number of patients at the infirmary was 363, and at the two semiconvalescent hospitals 113. The number of new outpatients was 20,109, and of casualties 15,969. In addition, there were 3128 new cases in the venereal department. Operations were performed on 5378 inpatients and on 3929 outpatients.

Congress of the History of Medicine.—The Congress of the History of Medicine, the second one held, will take place in Paris in the first week of June, and on the first five days of the week. The presidents will be Professors Jeanselme and Menetrier. The place of meeting will be the Faculté de Médecine and the opening ceremony will be undertaken by the Minister of Public Instruction on July 1. The subjects chosen for discussion, which will be held in the afternoons, are the history of hospitals and of public provision for the sick in all countries; the diet scales of man and the diet of animals in antiquity and in the middle ages; the history and nature of the great historical epidemics; the part played by pharmacists in the development of biology, and the history of epizootics. During the congress an exhibition will be open containing manuscripts, books, engravings, paintings, medals, and instruments of historical interest.

Cost of Rats.—Mr. A. Moore, director of the Vermin Repression Society, lecturing on May 23 last, at the College of Ambulance, London, said that the rat, which was the greatest enemy of man, cost at least one penny (two cents) a day to keep, and it had been proved that the rat was numerically as strong as the human race. Therefore, taking the population of Great Britain at 50,000,000, the cost of keeping rats was £75,000,000 (\$375,000,000) a year.

Vital Statistics.—According to the Registrar-General's return for the week ending May 14, 1921, the births registered in London and 95 other great

towns numbered 8996, corresponding to an annual rate of 25.2 per 1000. The deaths numbered 4434, equal to a death rate of 12.5 per 1000, as against 12.5, 12.5, and 12.4 in the 96 great towns in the three weeks preceding. In London 2068 births were registered, corresponding to a rate of 23.7 per 1000, and 1012 deaths, equal to a rate of 11.6, as against 12.6, 12.1, and 11.5 in the three weeks preceding.

Dental Treatment for Mothers.—At a recent meeting of the Surrey County Council the maternity and child welfare committee presented a scheme for providing dental treatment for mothers and children under five. The estimate was as follows: Twenty dental chairs, £1,000; dentures and fillings, £3,000; dentist salaries and traveling expenses, £700; total, £4,700. It is proposed at the outset to provide treatment at twenty of the school clinics already established by the education committee. The item of £3,000 estimated for dentures and fillings is based on the assumption that 360 women, being an average of six from each of sixty welfare centers, will need complete sets of new dentures. Toward the cost thereof mothers will be expected to contribute according to their means, and the committee will use every endeavor to secure the realization of this expectation. One-half of the net expenditure incurred by the council in connection with the scheme will be repaid by the Ministry of Health out of monies provided by Parliament.

This announcement is quoted here to show that local authorities, spurred on by the Ministry of Health, are making belated efforts to improve the condition of the teeth of the nation. The inhabitants of no country, perhaps, in the world possess such defective and diseased teeth as those of Great Britain. Examination of prospective soldiers during the war emphasized this fact. It is realized that sound teeth or, at any rate, a clean mouth are essential to a really good state of health. It is also recognized that in order that good teeth shall be general children's teeth and mouths must be properly treated. This is an important branch of preventive medicine. It may be further pointed out that child welfare centers have already fully justified their creation and are, indeed, the most necessary weapon in a campaign to prevent disease. But while the care of the teeth is obviously of the first importance, it must not be forgotten that such care does not consist wholly in mechanical means. Diet, after all, has much to do with the state of the teeth and mouth, and it is eminently desirable that the children of all classes in Great Britain should be trained as to diet. Knowledge of dietetics is sadly lacking in this country, and although, of course, it is absolutely impossible to lay down hard-and-fast rules with regard to food, general knowledge in this direction may be disseminated with hopeful expectations of satisfactory results. For example, a great deal too much saccharine material and pappy food are eaten by the young, to the lasting injury of the teeth, gums, and digestion. There is no doubt that an immense amount of good can be done by educational propaganda both by word of mouth and by the written word, with the object of preventing disease, by recommending diets,

nourishing and digestible, and which improve the teeth rather than hurt them. Proper diet in conjunction with skillful dentistry should go far toward insuring that the rising generation of Great Britain shall have teeth which will masticate efficiently and mouths which are not a constant menace to health on account of their septic condition.

TWO POSSIBLY DANGEROUS PRACTICES.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—Somebody has recently been advocating the exposure of hypertrophied tonsils and adenoids to the influence of x-rays through the mouth in order to diminish their size. This treatment may cure the hypertrophy, as the roentgenologist claims, but x-rays are always two-edged swords, as many have learned to their sorrow. It must be remembered that the pituitary fossa lies just above the pharyngeal wall, this structure and the upper wall of the sphenoid, both thin structures, are all the bony tissue between the pituitary gland and the rays. Radiation of healthy pituitaries must be harmful, especially in young children, just as radiation of healthy thyroids is harmful. Thoughtless and prolonged radiation, therefore, could produce a very serious hypopituitarism and this treatment it would seem is nothing but pernicious.

No doubt sausage and scrapple makers put into their product parts or all of ductless glands from motives of economy. Some of these tissues are not destroyed by heat, notably pituitary extract. But even though they may be rendered inert by heat, sausage is often eaten raw or partly cooked. A large dose of thyroid might thus be eaten by some one with hyperthyroidism with uncomfortable and deleterious results. The thyroid is sold as sweetbreads in many butcher shops. It seems wise, therefore, to forbid such indiscriminate and heterogeneous products as sausage in nervous and endocrinopathic people. Such food may explain unaccountable symptoms in them.

PODIATRY.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—The April 30th issue of the MEDICAL RECORD contains a letter from Dr. Armitage Whitman, commenting upon an editorial on "Podiatry" which appeared in the January 22 number of your publication. Those who have given attention to the care of the human foot will heartily agree with Dr. Whitman in his conclusion that it would be well for the medical profession to educate itself so as to meet the requirements for the intelligent care of the foot sufferers. "To-day," as Dr. Whitman states, "the medical schools do not impart adequate instruction along these lines," and "good courses in orthopedic surgery are even now rare." However, it is difficult to follow the Doctor's line of reasoning in connection with some other phases of his letter. The MEDICAL RECORD does not need assistance in supporting any opinion it may express, but I would venture to call Dr. Whitman's attention to the fact

that the editorial upon which he comments does not advocate "the giving of courses in medical schools to otherwise unqualified students who wish to gain a living by practising such a specialty," as he avers. Per contra, it urges the wisdom of having podiatry taught in undergraduate and in postgraduate schools which in turn means that legalized practitioners of medicine would acquire knowledge on this subject for the benefit of the public and for their own economic behoof.

Again, the Doctor refers to the term "podiatrist" as "self-styled." "Chiropody" is surely not etymologically or constructively correct. Hand and foot is not a proper designation for a foot practitioner. The word is probably a euphemism which developed from "chirug-podist." Why not "podiatry" instead?

Then, too, why should he group podiatry with cults, fads, isms, and pathies in medicine? Were he to visit the First Institute of Podiatry he would learn that the various branches of medicine basically necessary to comprehend the essentials of podiatry practice, are taught there by a staff of competent medical teachers, all of whom are licensed practitioners of medicine whose instruction is in perfect accord with the accepted medical truths of the day, and that the theoretic and the practical work, largely imparted by podiatrists, is in harmony with all that is most advanced in this field. I venture to state, without fear of justifiable contradiction, that there is no center in the country where more thorough instruction in foot orthopedics is given and where Whitman's theories of treatment and of practice are better and more scientifically exploited than in the clinics connected with the Institute, where as many as one hundred foot patients are nightly treated.

The highway to the road of health has many rough spots and some gaps. By educating a group of practitioners to do the increasing amount of foot work which the public requires because the general practitioner of medicine does not assume or attempt to assume this task, the pathway is made somewhat more smooth. Such is the mission of podiatry, and its usefulness will continue until the educational and professional standards for podiatry practice advance to the point where they run on all fours with the requirements for intending medical students; thereupon podiatry will become a legalized branch of medical practice and not an entity as it has been for all of the centuries.

Some of the leading practitioners of medicine are aiding the faculty of the Institute in imparting knowledge to their students. Their investigations have satisfied them of the good faith of those who are at the helm and of the need for this character of practice and practitioners. The State, through its Education Department and through its Legislature, has legalized the teaching and the practice of podiatry. "If the mountain will not come to Mahomet, Mahomet must go to the mountain." If medicine does not include the teaching and the intelligent practice of minor foot lesions, the podiatrist must lead the way to the proper care of this branch of medicine with the thought in mind that before long every licensed doctor of medicine must have acquired, in course, the knowledge essential to this character of work. M. J. LEWIS, M.D.

3. Cerebral Hemorrhage of the New-Born. Frederick C. Irving.
4. The Essential Factors of Cancer Causation. James W. Shannon.
3. Cerebral Hemorrhage of the New-Born.—Frederick C. Irving states that in over 12,000 consecutive births at the Boston Lying-In Hospital, the diagnosis of cerebral hemorrhage was made in forty-one cases, which is about once in 300 deliveries. This figure gives no proper idea of its frequency, as only those cases have been considered which were proved by autopsy or in which, during life, the signs of intracranial bleeding were unmistakable. Still-births and deaths from asphyxia, or from unexplained causes, were not included. Cerebral hemorrhage of the new-born may originate in at least three ways, according to the newer views: (1) from intrauterine asphyxia, (2) as one of the many manifestations of hemorrhagic disease of the new-born, and (3) from the trauma of either operative or spontaneous delivery. Since these children, should they survive the first few days of life, are very apt to become victims of cerebral paralyses or degenerate into hopeless idiots, it is absolutely necessary that the condition should be recognized immediately and every attempt made to prevent such a disastrous outcome. These babies, in the early hours or days of life, exhibit certain peculiarities which should not fail to attract the attention of the physician. They may have recurrent attacks of cyanosis and apnea, often without any other visible abnormality. This is especially apt to be the case in the subtentorial hemorrhage, where the extravasated blood causes an increase of pressure on the medulla and results in respiratory symptoms. Lumbar puncture, in these cases, will reveal bloody spinal fluid, and often the child will improve strikingly, for a time at least, upon the relief of pressure by this procedure. In other cases there is little to be noted at first, except that the child does not seem quite right. It refuses to nurse, and often has a characteristic, continuous and monotonous cry. Sometimes, on the contrary, it lies quietly and is difficult to arouse. As time goes on, nystagmus, inequality of the pupils, twitching, convulsions and spasticity of the extremities develop, and there may be retraction of the neck or opisthotonos. The anterior fontanelle is apt to show a varying degree of bulging, depending upon the degree of intracranial pressure. Edema of the face rarely occurred in the series studied. There may be protrusion of one or both eyeballs. The temperature may be markedly elevated, or it may be subnormal, or show no change whatever. The heart-beat is usually slow and forceful. If there is any question of intracranial hemorrhage, a lumbar puncture should be done. Prophylaxis is all important in this condition. Inertia, or lack of progress in labor, should be viewed with apprehension, and measures taken to hasten dilatation.

1. **High Blood Pressure Stasis.**—Arthur R. Elliott gives consideration to the clinical aspects of high blood pressure stasis, a term applied to a definite and clean-cut circulatory syndrome. Chief among the characteristic features are rapid pulse, gallop rhythm, and pulsus alternans. The pulse rate in his experience has been invariably rapid, although rhythm is usually regular or at most broken by irregularly recurring premature contractions. Auricular fibrillation rarely if ever occurs; it was not noted in any one of the fifteen cases which form the basis of this study. Some decline in pulse rate follows rest and recumbency, but the pulse rarely returns to normal frequency even after digitalization. It is a fair assumption that this rapid rhythm is an effort on the part of the ventricle to compensate by rapidity of stroke for reduced volume output. The serious significance of persistent increase in pulse rate in high pressure stasis has not been sufficiently emphasized. Other things being equal, a change from the deliberate, slow, and measured heart rate ordinarily present in high blood pressure to one more rapid than normal signifies the beginning of myocardial insufficiency. Pulsus alternans is a frequent development in these cases, and once present, is usually permanent. Of the fifteen cases studied eight displayed the alternating pulse. The serious significance of this development is indicated by the death of five of these patients after an average period of observation of seven and a half months. In four, deaths occurred from asystole; in one, from uremia. One of the most interesting and constant physical signs observed in high pressure stasis is the presystolic gallop rhythm. It was present some time during the course of all the cases studied. When the heart takes on this rhythm (not to be confused with the diastolic double sound so often heard in mitral stenosis) in high pressure stasis, it denotes grave muscle embarrassment. Once established, it never wholly disappears; and it has proved a sign of great significance. In high pressure stasis occurring as one of the phenomena of the terminal stage of chronic nephritis, blood nitrogen accumulation may attain high figures; whereas in non-nephritic cases but little waste nitrogen has been observed. The most striking characteristic of the blood pressure formula is marked and persistent elevation of diastolic pressure. Diastolic pressures as high as 180 mm. have been observed in the present series. Diastolic values attain their maximum in nephritic circulatory stasis. The nature of the causes which contribute to bring about this form of circulatory failure renders the prognosis a serious one, increasing in gravity according to the degree with which the vicious circle as between heart and arteries becomes more firmly established. Once edema appears, the end is not far off; and the presence of gallop rhythm, pulsus alternans, or Cheyne-Stokes breathing closes the door to any but temporary improvement. A more extended outlook on life may exist in the absence of nephritis. There are but three measures of treatment that appear to exercise any control in this condition, namely, rest, venesection, and digitalis.

3. **Röntgen Ray and Tuberculosis in Infants and Children.**—Frederick W. O'Brien and Forrest B. Ames give the following conclusions as the result of a statistical study of forty-four infants and children at the Boston Consumptives' Hospital. 1. (a) The von Pirquet and intracutaneous skin reactions are reliable guides to infection with tubercle bacilli, and the number of positive reactions increases from infancy up through childhood, over ten years of age, all patients reacting. (b) In twenty-six of thirty-six positive skin reactions, the roentgen ray disclosed the site of infection to be intrathoracic. 2. D'Espine's sign as a clinical index of tuberculosis of the bronchial lymph nodes is of relatively little value, being elicited only eleven times, as against roentgen-ray evidence of glandular enlargement in twenty-eight cases. 3. Three cases of positive sputum were found in fourteen diagnoses of chronic pulmonary tuberculosis. 4. Fourteen cases of chronic pulmonary tuberculosis of the adult type were found. This suggests that the so-called phthisis is

more common in children than has been stated by writers of textbooks. 5. Fifteen cases, negative clinically, showed definite roentgen-ray signs of marked structural changes consistent with tuberculous infection. This raises the question as to whether these children are to be regarded as more likely to develop clinical tuberculosis and should thus be watched carefully and roentgenographed at fairly frequent intervals.

10. **Contamination of the Hands and Other Objects in the Spread of Contagious Diseases.**—William J. Matousek holds that the pathogenic bacteria present in the secretions of diphtheria and scarlet fever may be cultivated from the surroundings of the patients, but in the former disease less often than in the latter. Improperly sterilized eating utensils may readily serve as carriers of infectious material. The thorough washing of the hands with soap and warm running water efficiently removes the secretions with which the hands may become contaminated. To facilitate this, the skin of the hands and nails requires special care in order to insure a smooth, healthy surface and freedom from any local condition which may render thorough cleaning difficult or impossible. Gauze masks protect the faces of the nurses from gross contamination with particles of air-borne secretions. Cultures from the hands of attendants are a useful check on the individual technique of those caring for contagious diseases. Cultural studies of the surroundings of patients with contagious diseases may serve to indicate the efficiency of the technique employed, and if applied at intervals they seem to stimulate attendants to greater efforts toward perfection.

3. **Report of the First Year's Work of a Clinic for Syphilitic Children.**—Reginald C. Jewesbury gives the findings of this clinic, held one morning a week in the Children's Department of St. Thomas' Hospital, London. During the first twelve months of its existence a total of 145 children were seen whose mothers were known to be syphilitic. Of these, nine mothers became infected after the births of their children, hence the disease in these children was acquired. Of the remaining 136 mothers, infected before the birth of the child, forty-seven had treatment before or during pregnancy. In 89 cases the mothers had received no treatment previous to the birth of the child. The following signs in the child are noted: (1) A few children of syphilitic mothers who had received no treatment were quite free from any sign, and have given negative Wassermann reactions even up to the age of ten to fourteen years. (2) Many children showed the usual signs seen in typical congenital syphilis, in whom rash and snuffles appeared two to eight weeks after birth. (3) In a certain number of children seen, in whom there was no history of previous symptoms, symptoms developed late, after the fifth or sixth year, i.e. "lues tarda." This group amounted to 10 per cent. of all cases examined. Lesions of the following structures were present: bones, periostitis; joints, synovitis; eyes, interstitial keratitis; brain, particularly affecting mental condition; ears, deafness; teeth.

4. **Similarity of Effects Produced by Absence of Vitamines and by Exposure to X-Rays and Radium.**—Cramer, Drew and Mottram do not agree that vitamins are necessary for the life of the individual cell. There is one tissue, however, which is specifically and profoundly affected by the absence of vitamins from the diet, namely, the lymphoid tissue. In mice and rats kept on a diet completely free from vitamins there is great atrophy of the lymphoid tissue, which is obvious even to the naked eye. The spleen is shrunk to a narrow ribbon; the thymus, which even in adult rats and mice remains relatively a large organ filling

the upper part of the thorax and covering the base of the heart, becomes so small as to be hardly visible. Microscopically these organs, especially the spleen, are found to contain very few leucocytes. The ordinary lymph glands may not be microscopically smaller than normal, but under the microscope are found to be almost bare of lymphocytes. The blood picture, as shown by a differential count, shows a reduction in the number of lymphocytes and an increase in the number of polymorphonuclear leucocytes. This condition of the lymphoid tissue is practically identical with that produced by exposure to x-rays and radium. These agents, if given in appropriate dosage, not only have the same effect as regards the lymphoid tissue, but they also produce the same general effect on the animals—they lose weight and die in a state of emaciation. The writers propose to investigate further the explanation of the problem of the production of the same effects by two apparently such dissimilar causes.

5. The Physiological Cost of Muscular Work Measured by the Exhalation of Carbon Dioxide.—A. D. Waller and Miss G. De Decker report observations which form part of a survey upon which they have been engaged during the last three years, of the physiological cost of muscular work measured by the expiratory discharge of carbon dioxide. This communication deals with the energy output (a) of colliers during their work at the coal face, (b) of shoemakers during their work at the factory. The relative energy output of colliers and of shoemakers comes out from these observations as three times greater for the former than for the latter, namely, 96 calories per hour per square meter of body surface in the case of colliers, and 32 calories in the case of shoemakers. The relation of their energy output to that of other workers whom the writers have measured during the last two years is exhibited in tables and graphs. For purposes of strict comparison it is necessary to state cost of work by individuals of different bulk in units per kilo of body weight, or preferably in units per square meter of body surface. But for practical purposes during investigation it was found useful to think in terms of CO₂ (gross) per second, which was translated at once into calories per hour by using the factor X 20. Their data are presented under both these forms in the graphs given.

6. Intermittent Albuminuria in Children.—F. Moor presents the following conclusions from the examination of the urine of 397 boys between eight and fourteen years of age at the Vauxhall Street Elementary School, finding albumin in 91 of the specimens (23 per cent.): (1) Intermittent albuminuria is a common condition among children. (2) It is not a form of kidney disease. (3) It is called by so many different names, and there are so many theories about it, that it is probably not a specific morbid entity but a symptom of several diseases.

4. Serious Reactions to Repeated Transfusions in Pernicious Anemia.—Harold M. Bowcock presents three

cases in which, after a large number of transfusions, there occurred extremely severe reactions following the transfusion of apparently compatible blood. These cases show the inadequacy of the present method of determining the compatibility of blood for transfusion, particularly in those cases in which the recipient has been the subject of a large number of earlier transfusions. The first patient had three admissions to the hospital during a period of 11 months, and received a little more than 10½ liters of blood in 17 transfusions. Eight times during this series she experienced reactions of varying degrees of severity, showing a marked hemoglobinuria on three occasions. Transfusion v gave one of the most severe reactions accompanied by hemoglobinuria, although only 20 c.c. of blood were injected. The same donor seems to have been used for the eighth transfusion, which was followed by no reaction except pruritis and discomfort about the eyelids. The patient's husband acted as donor six times, giving a total of 3,620 c.c. of blood, with one mild reaction, after Transfusion I, shown by urticaria and pruritis, and with one severe reaction, after Transfusion xv, shown by a severe shaking chill and an elevation of temperature to 106° F., but no hemoglobinuria; on four occasions his blood produced no reaction of any sort. Splenectomy gave no permanent benefit. After the reactions to Transfusion xv and xvi macroscopic matchings of the recipient's serum against the donor's cells were carried out with varying dilutions of serum and cell suspension; they were all negative for agglutination or hemolysis. The second patient had three admissions to the hospital in a period of two years, and received a total of a little more than eight and one-half liters of blood in 20 transfusions. He suffered nine reactions of varying degrees of severity. On no occasion was hemoglobinuria demonstrable. During the third admission the patient's son acted as the donor for small transfusions on two occasions; from the first transfusion there was practically no reaction, while after the second reaction the recipient's condition was critical. One donor was used three times; the use of his blood was followed once by chilly sensations and a slight elevation of temperature, and twice it produced absolutely no reaction. Splenectomy produced no permanent improvement in the patient's condition. The third patient had six admissions to the hospital in a little less than three years, and during this period received about eight and one-half liters of blood in 15 transfusions, and 235 c.c. of blood serum in one transfusion. She suffered six reactions of varying degrees of severity, showing hemoglobinuria on two occasions. From the time at which she first came under observation until the development of a marked cystitis, and later, the transfusion of serum, the blood picture showed very little regenerative activity. Whether the evidences of bone-marrow stimulation, shown by the blood picture, resulted from the cystitis and hypodermic injections, or from the transfusion of Group I serum, it is impossible to say. However, the picture shows greater bone-marrow activity following the administration of blood serum. The hemoglobin and R.B.C. determinations showed a progressive improvement until the time of death. The reactions in these cases must have been due to either: (1) imperfect technique; (2) unavoidable factors in the procedure of transfusion; (3) or some undemonstrable incompatibility of the blood used. The severe reaction is probably due to an anaphylactic manifestation and not to hemolysis *per se*.

5. The Fate of True Solutions (Phenolsulphonephthalein) and Colloids (Trypan Blue) Injected into the Mammalian Embryo.—George B. Wislocki investigated the fate of phenolsulphonephthalein and trypan blue injected into fetuses. Phenolsulphonephthalein was selected because it is a crystalloid, diffuses readily and is nontoxic. Trypan blue was used because it forms a colloidal solution, is relatively nontoxic and its behavior in the adult is well understood. The following are his findings from these observations: (1) Phenolsulphonephthalein, which represents an easily diffusible, non-toxic dye, is absorbed from the peritoneal cavity of the fetus. It passes slowly from the fetal blood stream through the placenta into the maternal blood stream and is excreted by the maternal

kidneys. It is also excreted by the fetal kidneys, since it is found in the fetal urine. This observation demonstrates that the fetal kidneys are capable of excretion, but sheds no light on the extent to which they act as a pathway of excretion before birth. No difference was noted between the cat and the guinea pig as to the time of transmission of the dye by the placenta, but a marked difference in the time required was observed in individuals of the same species. (2) Trypan blue, a less diffusible, nontoxic colloidal dye, is also absorbed from the peritoneal cavity of the fetus. It is not excreted in the maternal urine, and microscopic examination shows that it is not transmitted by the placenta to the maternal organism. It is excreted by the fetal kidneys. The observations with trypan blue show that the placenta is incapable of transmitting an inert foreign colloid from fetus to mother, and hence it is probable that the placenta does not transmit the colloidal products of fetal excretion unless they are first converted into simpler, readily diffusible, substances. (3) The fetus becomes vitally stained after injections of trypan blue into the fetal peritoneal cavity. The dye is stored in the endothelial cells of the liver, and also accumulates in the epithelial cells of the renal convoluted tubules. The dye is absorbed by clasmatoocytes which occur throughout the fetus and in the placenta and fetal membranes.

6. Demonstration of Plates Made with the Bucky Potter Diaphragm. E. C. Samuel and E. R. Bowie.
2. Acute Nephritis in Syphilis.—D. N. Silverman reports two cases of acute nephritis in which no arsenic or mercury had been given prior to the patients' coming under his observation. Being unable to account for any other etiological factor in either of them, the presence of syphilis prompted investigation to establish a possible relationship between the nephritis and the treponema.

1. Pericardiotomy for Suppurative Pericarditis.—Eugene H. Pool holds that the method described in this communication (resection of portions of the seventh, sixth, and fifth cartilages) meets the most important indications, namely, it opens the pericardium at its lowest part; involves little risk of injury to the pleura; provides ample drainage and allows such exploration as is necessary both at the time of operation and during postoperative course. If the condition of the patient warrants it this method is advisable, especially if a brief general anesthetic can be tolerated. In some cases a less extensive exposure may seem imperative. Under these circumstances resection of the sixth and

seventh cartilages seems best. The procedure was employed in a case reported by the writer, giving quite satisfactory exposure and providing efficient drainage. In conjunction with the Carrel-Dakin method it probably would prove adequate for many cases. Resection of the sixth cartilage alone may be done readily under local anesthesia and is tempting by reason of its simplicity, but the drainage is not satisfactory. The Carrel-Dakin method appears well adapted to the post-operative treatment of suppurative pericarditis.

11. Krukenberg Tumor of the Ovary.—Philip J. Reel recalls the fact that Krukenberg, in 1896, described a bilateral ovarian tumor to which he gave the name "fibrosarcoma ovarii mucocellulare (carcinomatodes)." He reports a case in which the tumor is similar to that described by Krukenberg, but presents very strong evidence of being metastatic in origin. This bears out the more recent investigations which tend to prove that, in the vast majority of instances, solid tumors of the ovary are secondary to a primary tumor situated elsewhere in the body. It is possible for these growths to attain enormous proportions in the absence of clinical manifestations. A review of the literature reveals that they occur most frequently before the age of forty, and that they are more malignant in character than is sometimes stated.

Le Progrès Médical.

February 12, 1921. xlix, 7.

Coincidence of Uremia and Pulsus Alternans.—Heitz refers to articles on this subject by himself and Esmein and by Chaler and Contamin. The latter arrive at conclusions somewhat different from those of the author. They report 10 cases, but the two conditions do not vary directly with each other in intensity. In but 7 of the 10 cases were both conditions in evidence at the time of examination. Of the other 3 cases examined 2 showed uremia with normal pulse and the third pulsus alternans with blood urea normal. Evidently the Lyons authors believe that the coincidence is more a matter of chance than necessity, while the author is inclined more to the latter hypothesis. He believes that, to say the least, the blood state in question is an important factor in the production of the pulse in question. The alternative involves the mechanical theory of the production of the latter. In his own material there was one case of alternating pulse in which azotemia was absent. He therefore is not committed to the view of a necessary sequence of the two symptoms. He believes, however, that the association should be studied persistently until it is cleared up. This must involve a long following up of patients, for the member of the association which is absent may appear in time. The presence or absence of a mechanical component—weakening of the ventricle from hypertension—must also be carefully sought. The author lays stress on the treatment-test, for by nitrogen poor diet the character of the pulse has often been favorably influenced. Naturally in these cases cardiac tonics are also given, but there is no warrant for stating that the two conditions indicate different plans of treatment.

Acquired Sexual Inversion.—Roubinovitch and Paul report the following unusual case: The man had been absolutely normal sexually up to the age of 20, when tuberculosis of the epididymis developed, for which both gonads were extirpated. From that period the subject was no longer attracted by women and developed an obsessive desire for the society of men. At the same time the psyche began to take on feminine characteristics. The authors have been unable to find any record of a parallel case, and if this case should prove to be what they claim, our knowledge of inversion and homosexuality will have to be revised. There is mention of opotherapy but it does not seem to have been used. Sonatically the man remained a perfect male, for unlike most castrates this one showed no development of female secondary sexual characters. It may be that this change will eventually develop, although some years have now elapsed since the alteration of personality.—*Le Bulletin Médical*.

Book Reviews.

THE SOCIAL DISEASES—TUBERCULOSIS, SYPHILIS, ALCOHOLISM, STERILITY. By Dr. J. HERICOURT, translated, and with a final chapter by BERNARD MIALL. London: George Routledge & Sons, Ltd.; New York: E. P. Dutton & Company; 1920.

UNDER the title of "Social Diseases," Doctor Hericourt discusses the public health situation with reference to tuberculosis, syphilis, alcoholism and sterility.

For tuberculosis, a semi-popular exposition of the etiology and pathogenesis of the disease is first discussed. This is followed by a presentation of the methods of attack against this scourge, including an outline of a campaign, the basis of which recommends the isolation of contagious sufferers. As for tuberculosis, so with syphilis, the etiology and pathology are presented, to which is appended a discussion of heredito-syphilis.

The next section is devoted to the study of alcoholism. It does not appear why alcoholism should be classed in a category with scourges of a purely infectious nature such as tuberculosis and syphilis, unless the connection be from the viewpoint of moral aberrancy. Doctor Hericourt's discussion of alcoholism is at this time more interesting to the French people than to the inhabitants of our country.

The final section is devoted to a discussion of the problem of sterility. It is obvious how important the problem of sterility may be to a country like France, where depopulation is extant. As a cause of falling birth-rate, natural sterility is considered less cogent than voluntary sterility or purposeful restriction of birth-rate. The proposed remedies are three-fold: moral, economic, and penal. Morally, the author recommends stemming the tide of feminism; economically, the imposition of tax upon celibates and unduly small families. These measures might prevent French depopulation, but they are such unusual innovations as to preclude serious immediate consideration for the conditions of many countries other than France.

The book is interestingly written and expounds the theme that civilized races are a prey to complex degeneracy arising from the hereditary taints of syphilis, tuberculosis, and alcoholism; and that all these morbid inheritances mutually act upon one another so as to produce a vicious cycle, of which sterility, voluntary or otherwise, is one of the results. In this light, sterility is viewed as a natural defense against the degradation of the race.

PULMONARY TUBERCULOSIS—A Handbook for Students and Practitioners. By EDWARD O. OTIS, A.B., M.D. Second Edition. Boston: W. M. Leonard; 1920.

WHAT was said in the MEDICAL RECORD by the reviewer of the first edition of this work may well be said of the second edition: "It is refreshing to get a moderate-sized volume on the vast subject of Pulmonary Tuberculosis in which essentially all that is known of it today is given in a precise, simple, and comprehensive form." To this may be added today that the enlarged and revised volume which the author modestly calls a manual and not a treatise, intended for students, practitioners, and patients, may be profitably read by the specialist. The addition to this second edition of the diagnostic standards of the National Tuberculosis Association and suggestive aphorisms from other authors has increased its value. A most interesting feature of the book lies in the arrangement, in that every chapter has an appropriate heading borrowed from general literature. The chapter on Hamlet is very aptly headed by the quotation from Hamlet:

"Find out the cause of this effect.

"Or rather say the cause of this defect.

"For this effect defective comes by cause."

The motto by Pryor is equally well chosen for the final chapter in which the author recalls interesting cases:

"Examples draw when precept fails,

As sermons are less read than tales."

The book is well printed and well bound. The chapters on anatomy, physiology, and pathology are illustrated by good drawings. Excellent portraits of Koch, Laennec, and Auenbrugger adorn the pages. If there is any criticism, one might perhaps say that in the

paragraph dealing with the arrangements for treatment outside of the sanatorium there is a lack of reference to simple fresh air devices. The author only gives illustrations of sleeping balconies, porches, and tents, and although these devices may be easily installed in country houses and small towns and in rare instances on the roof of a city house, the vast majority of the consumptive poor in large cities could certainly not avail themselves of such constructions. The only outdoor sleeping devices of which the tenement dweller in large cities can avail himself are the aerarium devised by Bull, the window-tent devised by Knopf, or some of the modifications of these which have since been put on the market. A short description of such devices would materially add to the usefulness of the book.

PRACTICAL BACTERIOLOGY, BLOOD WORK AND ANIMAL PARASITOLOGY, including Bacteriological Keys, Zoological Tables, and Explanatory Clinical Notes. By E. R. STITT, A.B., Ph.D., M.D., Sc.D., LL.D., Rear Admiral, Medical Corps, U. S. Navy; Commanding Officer and Head of Department of Tropical Medicine, U. S. Naval Medical School; Graduate, London School of Tropical Medicine; Professor of Tropical Medicine, Georgetown University; Professor of Tropical Medicine, George Washington University; Lecturer in Tropical Medicine, Jefferson Medical College; Member, National Board of Medical Examiners; Member, Advisory Board Hygienic Laboratory; Formerly Associate Professor of Medical Zoology, University of Philippines. Sixth Edition, Revised and Enlarged, with 1 Plate and 177 Other Illustrations, Containing 637 Figures. Philadelphia: P. Blakiston's Sons & Co., 1920.

SEVERAL features, aside from the body of the text, render this small volume a veritable "first aid kit" for the student, for the beginning practitioner and practical laboratory worker, and for the one who does laboratory work only occasionally. The table of common communicable diseases, which occupies the inside of and first page of fly-leaf, is a ready reference concerning cerebrospinal meningitis, chicken-pox, diphtheria, German measles, measles, mumps, poliomyelitis, scarlet fever, smallpox and whooping cough, with respect to cause and source; incubation period; mode of transmission; period of communicability; laboratory diagnosis; salient clinical features; and methods of control. The ruling of the Turk disc and the explanation of the squares given on the reverse side of the fly-leaf, is another of these utilitarian features. The occasional laboratory worker will find abundant help in the sixty-nine pages which constitute the appendix, and which include the preparation of tissues for examination in microscopic sections, and various other laboratory procedures. The body of the text conforms to the original plan, but is enlarged by seventy-two pages and a number of new illustrations. A new chapter, giving in tabular form the various protozoal, helminthic, and arthropod diseases, is added, and the sections on streptococci, blood flukes, and the influenza bacillus have been rewritten. The section on diseases of the hemopoietic system has been revised and classified under the headings of polycythemias, the primary anemias, the secondary anemias, the leucemias, the pseudo-leucemias, and the splenomegalies. Other additions and changes, notably the enlargement of the table of anatomical normals to include every important organ, and the modification of the section on blood chemistry to include the more recent methods, bring the work up to date.

KOMPENDIUM DER AUGENHEILKUNDE für Studierende und Aerzte. Von Prof. Dr. PAUL SILEX. Geh. Medizinrath in Berlin. Elfte und zwölfte verbesserte Auflage. Berlin: S. Karger, 1920.

THIS little manual first appeared in 1891. In the present edition the author has incorporated everything from the special literature which might add to the value of the book and notably new methods of treatment and new medicaments. Some of the purely theoretical sections have been condensed. Numerous colleagues have assured him of the practical worth of the volume, and he trusts that the new edition—this being the combined eleventh and twelfth—will maintain this favorable judgment.

THE COURSE OF OPERATIVE SURGERY: A HANDBOOK FOR PRACTITIONERS AND STUDENTS. By Prof. Dr. VICTOR SCHMIEDEN, Lately Assistant in the Royal Surgical Clinic in the University of Berlin; Professor of Surgery in the University of Halle; and ARTHUR TURNBULL, M.B., Ch.B. (Glasg.), Lately Demonstrator of Anatomy in the University of Glasgow. With a Foreword by Prof. Dr. A. BIER. Second Enlarged English Edition. New York: William Wood & Company, 1920.

So far as topographical anatomy and technique are concerned, we find operative surgery presented in a most palatable form in this book. This is not merely a composite edition, or rehash, of the text of scores of other authors, but there is an individuality about it that is almost immediately impressed upon the reader and stamps it as far different from the average textbook on this subject. In fact, the reader almost feels that he is to perform operations under the personal supervision and guidance of Professor Schmieden; for not only is the bare technique of individual operations given, but also there are almost constant comments such as might be given at an operative clinic with a live patient on the table. The book is written more in conversational than in ordinary textbook style, which again tends to make it a live work rather than a dry epitome of operative directions.

As Turnbull says in the Introduction, "The work will assist the student to bridge the gap that exists between anatomy and surgery by affording him a connected and scientific survey of modern operations." This book, of which six editions have appeared in the original, is an anatomical reconstruction in English of the main facts of the operative course when Schmieden was assistant to Professor Bier. The English edition was revised after a trip to Berlin for the express purpose of revision in the light of a series of operations conducted under Schmieden's personal direction.

Beginning with the section giving typical ligations of arteries, and so on throughout the book, concise directions are given as to the methods of performing the more common operations. When there are a number of methods in vogue the author has selected one or more of those which he believes best. His choice of methods is, in our opinion, generally good; but there are some serious omissions and occasional instances where much better methods are now commonly employed in this country. For example, the methods described for kidney fixation were long ago superseded here; the incision for breast removal is placed too low in the axilla, so that scar tissue is apt to restrict abduction and elevation of the arm; there is no description or reference to the Polya or Balfour methods of stomach resection; in the operations for cholecystostomy first place is accorded to that in which the fundus of the gall-bladder is stitched to the parietal peritoneum—a procedure which was almost universally abandoned here many years ago.

However, in spite of these faults and rather numerous typographical errors, this is an excellent textbook and one from which the student will learn much more than the bare technique of operations.

MENTAL SELF-HELP. By EDWIN L. ASH, M.D., B.S., M.R.C.S. Author of "The Problem of Nervous Breakdown." New York: The Macmillan Company, 1920.

To those who are weary of spirit and downcast in mind from various causes, which there is no need to enumerate here, this little book is generously offered. Modestly, yet with a firm conviction, the author gently leads the reader from the darkness and dreariness of a "blue outlook" to the sunshine and hope of a perfected faith in the balance of life, if we but use the means at hand to obtain it.

The book treats of mind and health, self-control (how to obtain and hold it), self-suggestion in theory, self-suggestion in practice, right and wrong thinking, and conclusions, in which he says: "We are all students of Life and Health: let us meet on common ground whenever possible and devote our strength and time to bringing together the facts of our experience gathered in many places. Physician and psychologist; mind-healer and psychoanalyst; suggestionist and healer through prayer; priest and layman—let us contribute

our findings to the common store of knowledge, endeavoring to harmonize those things which we have proved and hold fast to, without ever encouraging those differences of opinion which grow so soon into antagonisms. Let us seek each his neighbor's good." "The object of this book is not to lead people to desert their doctors for self-treatment, but to help them obtain a means of support which shall be of great assistance in times of sickness and mental distress."

A particularly interesting chapter is the one on self-control in which there is pointed out the many ways through which our energies are wasted and the means whereby we can conserve the same energies to use for greater efficiency, happiness, and general poise and health.

BLOOD PICTURES: An Introduction to Clinical Hematology. By CECIL PRICE-JONES, M.B. (Lond.). With 5 Colored Plates and 3 Illustrations in the Text. Second Edition. New York: William Wood & Company, 1921.

THOSE who are acquainted with this excellent little guide to blood examination will be glad to learn of the appearance of a new edition. The changes in this one are not many. A report on some recent work by the author on the sizes of red cells has been added, and the new Bürker-Hawksley counting chamber, which is an improvement on the old Bürker apparatus, is described and pictured. The plates, which are beautifully executed, depict normal and abnormal red cells, lymphoid cells, leucoid cells, abnormal white cells, and marrow cells. The work is divided into two parts, the first dealing with the technique of blood examination, a description of the blood cells, and the normal blood picture; the second containing chapters on the blood pictures in bacterial infections, protozoal infections, blood diseases, and malignant diseases.

VITAMINES, ESSENTIAL FOOD FACTORS. By BENJAMIN HARROW, Ph.D., Associate in Physiological Chemistry, College of Physicians and Surgeons, Columbia University. New York: E. P. Dutton & Co., 1921.

DR. HARROW has aimed at writing a popular presentation of a subject which has engaged the attention not only of the scientific world, but also of the general public. It is natural that public interest should be aroused as to the essential factors of food; it is important that such interest should not be deceived. Dr. Harrow has succeeded in presenting a view which gives all information, which has the merits of common-sense application and is not written in the fashion of a quick advertisement. The theories and the facts of vitamin research are clearly and ably presented, with their presence in foods and the relation to caloric food-factors. Hence anyone with any power of mental application can choose a pleasant and efficient diet; and a book so well and sanely balanced as this should be in the hands of all teachers of domestic economy and hygiene for the promotion of the health of the growing families and the confusion of the food profiteers with their dried and canned fruits and vegetables, as opposed to the fresh foods of the garden.

A MANUAL OF SURGERY for Students and Practitioners. By Francis T. Stewart, M.D. formerly Professor of Clinical Surgery, Jefferson Medical College; Surgeon to the Pennsylvania Hospital. Fifth edition, with 590 illustrations. Philadelphia: P. Blakiston's Son & Co., 1921.

THE characteristic of this work in its several editions has always been its simplicity and the clarity of its descriptions. It was written, not for the experienced surgeon, but for the student and the recent graduate, and for the general practitioner in rural practice on whom the necessity falls of caring for surgical cases and even of operating occasionally. Such a man could not have a better guide than this book. The regrettable death of Dr. Stewart has thrown a portion of the revision for this fifth edition (though the greater part had already been done by the author), and also seeing the book through the press on Dr. Walter E. Lee. A careful inspection shows that this work has been excellently done, and in such competent hands the book so solidly established by Dr. Stewart should live through many editions yet.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

*Seventy-Second Annual Session, Held in Boston,
June 6-10, 1921.*

(Special Report to the MEDICAL RECORD.)

HOUSE OF DELEGATES.

First Day—Monday, June 6.

DR. DWIGHT H. MURRAY OF SYRACUSE, N. Y., SPEAKER
OF THE HOUSE, IN THE CHAIR.

Address of the Speaker of the House.—Dr. DWIGHT H. MURRAY of Syracuse, N. Y., delivered this address in which he dwelt upon the profession's new conception of publicity. Ethical exclusiveness which had characterized the deliberations of professional men in the past appeared to be vanishing, and the new idea was that the general public should be given more information about preventive medicine. The physicians should take the public into their confidence in larger measure than they have done in the past. Dr. Murray proposed the establishment of a Lay Health Journal through which the medical profession would undertake to give an authoritative link between the profession and laity, printing medical news for the layman to enlighten him on matters of medicine, dealing particularly with preventive medicine, social hygiene, medical survey of industries, medical legislation, sanitation, communicable diseases and the like. He suggested that this matter might be taken up with the Surgeon General of the Public Health Service in Washington, partly with a view toward financing the proposition.

Protection was the one and only thing that we get from our Government, he said. Surely this kind of protection was the very best and if properly presented would do away with much if not all thought of so-called Health Insurance and other maternalistic plans that were continually being brought forward by some misguided philanthropists. Education in all fundamentals of hygiene and health matters was the greatest protective measure and why should we not through Congress give this protection to the people at large? Let Congress be memorialized if necessary and follow it up actively to obtain a full department of public health as had been recommended by others which if granted would solve the Public Health journal question. Dr. Murray said that the influence of more than 85,000 members of this association should have weight enough with their individual legislators to put such a law through without question.

The answer of the medical profession to the nation's need in time of war, when two out of every three medical men in this country offered their services in some capacity, ought to vouchsafe the much-needed Department of Health; they did a service worth while, at great personal sacrifice. Surely these men could be trusted with the management of such department. Another plan that might be followed in case of the non-feasibility of the one mentioned, that would not need a journal, would be to appoint editors and create a demand for a medical feature section of the 900 great Sunday papers in this country, taking a different subject or different phases of a popular subject for each issue. These were child welfare, tuberculosis, cancer, personal hygiene, communicable diseases, and like topics. Let one associate editor be responsible for one feature section each three months. It should be ready and in the hands of the publisher at least two weeks before, and released to only one paper in a given section of the country. When this had been made popular, a demand would have been created that could not be satisfied except by giving more, and our Public Health Journal would be an established fact without large expense and would be read by millions. It might be made so popular that it would finance itself. Another matter that was being thoughtfully considered was the employment of one or more field secretaries, who might be of great assistance in building up our association by putting all medical men in closer touch with it and letting the different branches know more of the important details of the working of our very efficient

home office in Chicago. In order to learn what the attitude of our constituent members was on the two questions above mentioned, he had consulted by letter the various State societies through their secretaries and had received many answers, and with one exception both these projects were unanimously indorsed, to be made effective when our resources warranted. The activities of the American Medical Association were many and the members of this House were here for serious business; it should be cared for with even greater diligence than our own private affairs. He therefore urged that each member of this House not only attend every session but that he pay such strict attention that he could explain to his home society the reasons for each action taken by the House.

Address of the President-Elect.—Dr. HUBERT WORK of Pueblo, Col., made a brief address in which he emphasized the duty of the medical profession to educate the public in the prevention of disease. He declared that the achievements in medicine had been hidden from the public in the past because there had been no means for displaying them, so that the people for whom the medical researches and medical discoveries were made heard nothing about it. Medicine should be advertised, said Dr. Work. It should be popularized. Much more work should be done by the health authorities along these lines. State societies should have paid secretaries who could give their full time to the work, and the A. M. A. should have a staff of paid secretaries to do organization work. Dr. Work then made a strong plea for the establishment of a department of health and public welfare in the Federal Government as provided in Senate Bill 1039 or Senate Bill 1607.

Report of the Secretary.—Dr. ALEXANDER R. CRAIG submitted this report, in which it was stated that the membership of the several constituent associations which constituted the membership of the American Medical Association, in May 1, 1921, was 84,971. The fellowship of the Association on May 1, 1921, was 50,870, a net increase for the thirteen months covered by this report of 3,925. The report recorded that Dr. Isadore Dwyer, Vice-President of the Association, died in New Orleans on October 12, 1920. At its meeting in November the Board of Trustees elected Dr. Rudolph Matas, New Orleans, to fill the unexpired term. Dr. Dwyer at the time of his death was also member of the Council on Medical Education and Hospitals. Surgeon General Merritte W. Ireland was appointed, *ad interim*, to fill the vacancy. The report then called attention to the fact that conditions which had developed subsequent to the world war had affected the Association in very much the same manner as they had affected other organizations. The reaction from the altruistic and patriotic motives which controlled actions during the war had had its influence upon the esteem in which some physicians held the principles which had always been the basis of the policies of this Association. One of the dangers which merited the consideration of the House of Delegates was the apparent tendency on the part of certain physicians and a few component county societies to be dominated by commercial ideals rather than by the standard which the Association had adopted in formulating its principles of Medical Ethics. The opening statement of these principles was: "A profession has for its prime object the service it can render to humanity. Reward or financial gain should be a subordinate consideration." This subject was presented to the House of Delegates because, as representatives of the organized medical profession, the members of the House were in a position to carry back to the component societies influences which should correct these destructive tendencies. Attention was called to inactivity on the part of some component societies and to the fact that in certain localities, there had been evidence of a lack of coordinated action and failure to appreciate the essential unity of all branches of the organization.

While it was recognized that each component society was an entity and competent to act for itself, it was essential that the component societies in each state should actually be federated and should cooperate with each other in carrying on the work of the organized profession, first within the county

and then within the State. The same principle must hold in the relationship which exists between the constituent association and the national body. The best work could be accomplished only when an undivided, loyal cooperation existed between all branches of the organization. One of the most effective measures for carrying out the purposes of the organized medical profession was the education both of its members and the lay public regarding questions relating to the health and physical welfare of the community. When action was taken without gaining the support of public opinion in the community, it was not unusual for failure to result. If the members of the House of Delegates would urge the organizations which they represented to be active in informing the influential citizens of their several communities regarding matters which affected the preservation of health and the treatment of disease, the results undoubtedly would be that the people themselves would appreciate more fully the value of laws regulating health conditions and controlling the practice of the healing art so that the public rather than the medical profession alone would demand these laws and would require their enforcement. The report contained the suggestion that inasmuch as it was a serious matter to commit the Association on certain questions in the short time of an annual session, that if the House deemed it wise provision might be made so as to make it the function of one of the existing Councils to investigate scientific questions that might be brought before the House and to report back recommendations for action.

Report of the Board of Trustees.—Dr. A. R. MITCHELL of Lincoln, Neb., submitted this report which showed that their publication department was affected in the same way as were other printing establishments. While operating at a loss during the first part of the fiscal year, they were able to show a net gain of \$30,000 since last August. The records of the subscription department showed that during the year 1920 4,110,112 copies were printed—349,761 more than in 1919. The weekly average was 79,040, an increase in the weekly average of 6,726 over 1919. The circulation of the Spanish Edition was increasing, being 3,611 for 1920, as against 2,908 a year ago. There was no doubt that the publication of this journal was doing much good; it was bringing the Association as well as American Medicine, prominently and most favorably to the attention of the best physicians in the Pan-American countries, was developing a friendly spirit and was bringing to this country as students and for post-graduate work many who otherwise would be going to European countries. All the special journals were doing well, so far as circulation was concerned though all were being conducted at a loss with the exception of the Archives of Internal Medicine. Under the conditions that were prevailing the Board felt that it was wise to discontinue the combination rates on the special journals, and in some cases to increase the price. One of the great opportunities for the advancement of scientific medicine in the United States was the encouragement of these special journals. While they should not publish such journals at a loss, they should be issued at as near cost as possible. The Cooperative Medical Advertising Bureau had closed its seventh year in December, 1920, and its reports showed that it was becoming increasingly helpful to the State journals each year. All the State-owned medical journals, except Illinois, were now represented by the Bureau. The Board of Trustees had decided to postpone the erection of a new building which was badly needed because of the overcrowding of the Association headquarters, owing to the present high cost of building projects.

The Committee on Rehabilitation of Ex-service Men, appointed by the Board of Trustees, reported that early in March the Committee on Hospitalization of ex-service men of the American Legion, through Dr. Billings, requested a conference with the American Medical Association attending the Congress on Medical Education and Hospitals, Licensure and Public Health, then being held in Chicago, with the object of securing the co-operation of the American Medical Association looking to the improvement of the unsatisfactory condition of affairs in the hospitalization and care of disabled ex-service men. A committee was appointed and proceeded to Washington where conferences were held with

the Surgeon General of the Public Health Service, the officers of the Bureau of War Risk Insurance and with others, making a preliminary and general survey of the whole subject. Meantime Dr. Billings had been selected by the Secretary of the Treasury as a member of the Board of Consultation on hospitalization of ex-service men. It was decided that as Dr. Billings was a member of an official government committee he could represent the Committee of the American Medical Association unofficially but effectively. Hence the Association's committee had ceased work awaiting further developments.

The Propaganda Department continued to be a clearing house for information relative to the nostrum evil and quackery. Letters running into the thousands were annually received and answered by the department, in addition to the reports that appeared in the pages of the *Journal*. There was an increasing number of inquiries coming from schools and colleges owing to the fact that this propaganda work had come to be recognized to such an extent that it was referred to in school and college textbooks. The influence that the department was exerting in the interest of truthfulness and honesty in medical matters as they affected the public directly would never be generally known; but to those who were familiar with the facts, this feature of the department's work was especially encouraging and impressive. An active demand continued for the pamphlets, books, educational posters and stereopticon slides prepared and issued by the department. The same was true of the educational posters on the nostrum evil; these were reprinted from time to time with modifications and additions that brought them down to date. The new edition of "Nostrums and Quackery" which had been delayed was not practically ready for distribution.

The Council on Pharmacy and Chemistry was continuing the work which had put the profession of this country far ahead of that of any other, in that it was protected against misrepresentation and commercialism inherent in the exploitation of proprietary medicines. The fact that this country was better off in this regard than others was obvious to those who would compare the advertisements of medical products in even the high class medical journals of Europe with those of this country. That much had been accomplished would be evident if one compared conditions of twenty years ago and now. The problems of the Council to-day were radically different from those which existed when it was first organized. In the early day they were to a large extent concerned with secret and semisecret complex mixtures of simple drugs exploited to the profession under fanciful names and with extravagant claims. These had been forced into obscurity, and the physicians who still prescribed them were reticent about it. In the place of these nostrums we now had biologic products, and biologic therapy was tending toward conditions just as serious as those which resulted from the exploitation of shotgun mixtures; and they were more dangerous. One must be on guard against the present commercial exploitation of this form of therapy. Another development in therapeutics somewhat related to the field of biologic therapy was the intravenous use not only of biologic products, but also of drugs and chemicals—a method of treatment which had numerous dangers. These newer problems which were engaging the attention of the Council should also concern every physician. New and Non official Remedies was the official publication of the Council issued annually. This book contained a list of proprietary products accepted by the Council, and physicians might protect themselves by having this book available for reference. The Council also published the *Useful Drugs Epitome of the Pharmacopœia*. It also had a Committee on Therapeutic Research, to which the trustees make an appropriation each year. This appropriation was used for investigation and laboratory research into the action of drugs and pharmaceutical products.

The Committee on Scientific Research, which was constituted in 1900 and continued until 1914, when it was found necessary to discontinue the appropriation, was reestablished in 1918 and given an appropriation of \$1,200; a similar appropriation was made in 1919; an appropriation of \$1,500 was made in 1920 and 1921. The board of trustees was still of the opinion that this expenditure was well worth while.

Report of Judicial Council.—Dr. M. L. HARRIS of Chicago submitted this report, which recalled that at the New Orleans session of the House of Delegates a resolution was adopted requesting the Judicial Council, at the next annual session, to report a "concrete proposition" or plan for reducing the number of trustees of this association from nine to seven and to subdivide the United States into seven trustee districts. The plan now submitted was that in 1923, when the term of office of three trustees expired, one trustee be selected for a term of seven years. In 1923, when the term of three more trustees expired, one trustee be elected for seven years, one for five years, and one for four years. In 1924 there would be four holdover trustees for terms of six, five, four, and three years respectively, with three to be elected, one for a term of seven years, one for two years, and one for one year. In 1925 there would be six holdover trustees for terms of six, five, four, three, two, and one year respectively, with one trustee to be elected for a period of seven years. Thereafter there would be one trustee to be elected each year for a term of seven years. Before this could be done changes would have to be made in the articles of incorporation. The House of Delegates could direct the Board of Trustees to have these changes made any time during the coming year, but the change in the constitution would have to be made this year and lie over until next year before it could be adopted and become active. A plan was also submitted for the division of the United States into seven trustee districts, in such a way that no one State would have the majority of delegates in the district in which the State was included. These plans were presented to the House, not as a recommendation from the Judicial Council, but in response to the action of the House of Delegates requesting the Judicial Council to propose a plan. During the past year a case had been submitted to the Judicial Council for adjudication. This was an appeal from the Spokane County Medical Society from an action of the Washington State Medical Association. The question raised did not seem to warrant the calling of a special meeting of the Council, especially in view of the short time intervening between the next regular meeting at the annual session. A supplementary report was therefore presented on the case, stating that the Spokane County Medical Society had passed resolutions changing its by-laws to prohibit contract practice, defining contract practice, and making provision for the expulsion from the society of any man guilty of contract practice. Two members appealed to the State Society and the State Society ordered the County Society to rescind the by-laws affecting this matter. The Spokane County Medical Society then appealed to the American Medical Association. The Judicial Council had decided that the Spokane County Medical Society was within its rights when it passed these by-laws. That a local society was within its rights in passing bylaws governing the qualifications of its members, provided such bylaws did not conflict with the bylaws of the State Society and the bylaws of the American Medical Association. The doctors who appealed to the State Society were also within their rights on the well recognized principle of declarative law and medical justice. The Judicial Council believed the Washington State Medical Society exceeded its powers.

Report of Council on Health and Public Instruction.—Dr. VICTOR C. VAUGHAN presented this report, which stated that the Council had continued to develop its program adopted in 1914, namely: (1) Investigation of existing health conditions with a view to securing accurate information on all phases of the public health situation. (2) Education of the public and the profession by every means within the resource of the Council, in order that the public might understand the advance of scientific medical knowledge and the possibility of utilizing such medical knowledge in the prevention of disease, the reduction of the death rate, and the preservation of human lives. (3) The crystallization of public sentiment into such practical health laws, regulations, and ordinances as might be necessary for the conservation of human life. The report dealt with the reorganization of Federal Public Health activities and stated that efforts were being made to secure information regarding the plans of the committee appointed to consider the reorganization of the executive

departments of the Federal Government, and whether they were taking up public health as one of the first subjects to be considered; whether it would consider this subject in committee of the whole or would appoint a subcommittee thereon. During the Presidential campaign of 1920 Senator Harding repeatedly stated in his speeches that he regarded public health and human welfare as two of the most important subjects for governmental activity and that, if elected President, he would favor the creation of a Department of Health and Welfare with a secretary in the Cabinet. Following his inauguration he commissioned his personal physician, Dr. Charles E. Sawyer of Marion, Ohio, as Brigadier General in the Medical Reserve Corps and assigned to him the special duty of collecting evidence and preparing plans for the development of the health and welfare work of the Federal Government. With the termination of the Sixty-sixth Congress on March 4, 1920, all measures before both houses at that time were wiped off the calendar. Since the reassembling of Congress some nineteen House bills and nine Senate bills affecting public health had been introduced. In the co-ordination of voluntary health activities definite progress had been made in the course of the year. During the summer of 1920 a survey of existing organizations was made by Dr. Donald B. Armstrong of the National Tuberculosis Association under the direction of the American Red Cross and the National Tuberculosis Association. Data were collected and plans for co-ordination were discussed at conferences and by correspondence, with the result that an informal congress was called at Washington on October 18, 1920, at the Red Cross headquarters, which was attended by representatives of a number of organizations. At the December conference the National Health Council was organized, officers were elected, and an appropriation of \$30,000 for two years made by the American Red Cross. It had taken offices in the Terminal Building in New York and all the organizations composing the National Health Council had headquarters under the same roof, with the exception of the American Medical Association, the American Red Cross, and the State Health Officers' Association. The National Health Council was proceeding slowly and was developing a marked spirit of co-operation, which, it was hoped, would result eventually in working out a common plan of procedure. Applications from a large number of organizations were now being considered and plans were being developed for securing financial support for a constructive program. This Council reported definite progress during the past year in the matter of vital statistics legislation. In 1906 when its work was undertaken only ten states in the Union had effective laws for the registration of deaths and only eight states had any laws requiring the registration of births. From 1906 to 1920 the Model Bill, developed by the Council in cooperation with the Division of Vital Statistics of the United States Census Bureau and other contributing organizations had been adopted by forty-five states. With only three states still to adopt this measure, the end of this work to which the Council and the Association had materially contributed in the last eighteen years was clearly in sight. During the past winter bills for the prevention of animal experimentation were introduced in four states, namely, Massachusetts, New York, Indiana and Maine. These bills all failed of passage. For the first time in the history of efforts to abolish animal experimentation an appeal was made last November in California to popular vote through the use of the initiative. The proposed legislation provided for the strict abolition of all animals for experimental purposes within the State of California. The campaign was conducted intensively by both proponents and the opponents of the measure. At the final vote it was defeated by a majority of approximately 250,000. The report announced that plans for the work of the Eye-Conservation Council were now being formulated. The Committee on Cooperation of the National Education Association of the Council submitted a separate report, setting forth the work done at their conferences.

The *Sub-Committee on Amendments to the Harrison Act*, of which Dr. HAVEN EMERSON was chairman, submitted a separate report, in which the opinion was expressed that in view of the information at

hand, it was deemed wise to defer to a later date attempts to arrive at any quantitative estimation of the need of habit-forming narcotic drugs in the United States. The purpose and scope of the Harrison Law were such that it was in effect an excellent and desirable means of control by the Government of the abuses incident to trade in the habit-forming narcotic drugs. There should be no ambiguity in the interpretation of its requirements by the medical profession, though under the cover of the words, "in the course of his professional practice only," some had maintained that exemption was granted to physicians to prescribe or dispense habit-forming narcotic drugs to addicts. Decisions of the courts thus far rendered had uniformly served to strengthen the obvious conclusion that such use of the professional privilege did not constitute proper professional service. There should be made an important modification of the law by Congress, to remove the tax burden on the medical profession which is imposed upon physicians without compensatory return. Since the Harrison Law was in the interest of the public generally, and not taxation of physicians as a class, such class legislation was unfair to the medical profession as well as an unsound economic policy. The amount of money collected under the Harrison Law in 1920, was \$1,513,919.15, a sum far in excess of the amount appropriated by Congress for its enforcement. In view of the fact that the same unit of the Internal Revenue Bureau was charged with the enforcement of the Narcotic Drug Law and prohibition, and inasmuch as the latter required a much larger appropriation and occupied a larger share of the public attention, it was feared that the important duty of efficient enforcement of narcotic drug laws might be neglected. Therefore the committee recommended that the American Medical Association urge the appointment by the Commissioner of Internal Revenue of a special deputy commissioner in charge of a separate unit for the enforcement of the narcotic law, and that due prominence be given to that service in the accomplishment of its effective functioning. The committee further recommended that the Harrison Law be supplemented in the several states by uniform state laws, in harmony with and supplemental to the Harrison Law, should base their control of any medical abuse of narcotic drugs on those powers possessed by the states to punish crime as well as to revoke licenses to practice medicine, dentistry, pharmacy or veterinary medicine. An outline of a modern state law was presented. Such a law need not be a tax law; in fact the taxing feature should be abolished. The regulations and details of administration under the two laws should be parallel in order to avoid confusion, and the machinery of enforcement of a state law should be as simple as possible consistent with effective operation. Unnecessary duplication of records under the Federal and State Law should be eliminated, the state accepting the records kept under the Harrison Law. Power to make and enforce special regulations of any sort, except those absolutely necessary in administrative application of the law, should not be entrusted to state officials. Those regulations considered necessary should be submitted for approval, before being promulgated, to the State Medical Board or other professional body of competent jurisdiction and to the Attorney General of the State. The institutional care and treatment of addicts unable to pay for such care and treatment should be provided for by a state law. The committee recommended that the American Medical Association urge both Federal and state governments to exert their full powers and authority to put an end to all manner of so-called ambulatory methods of treatment of narcotic drug addiction, whether practiced by the private physician or by so-called narcotic clinic or dispensary. In view of the fact that habit-forming narcotic drugs had definite valuable and indispensable uses in the practice of medicine, there should be permitted no encroachment on the right and duty of the physician to exercise his judgment unhampered in the legitimate use of such narcotic drugs. Therefore, the committee recommended that the bills now before Congress which proposed to limit the total amount of narcotic drugs which might be imported into the United States be disapproved, and their passage opposed by

the American Medical Association, for the reason that such legislation at the present time would inevitably make these drugs more expensive and difficult to obtain for proper medical purposes; and that such limitation of the total supply would certainly encourage smuggling of habit-forming drugs into the United States. The committee also recommended that the several state and county medical societies be urged to obtain on their own initiative and through their own officers, such information as might be necessary to bring about the effective prosecution by local, state and federal authorities, of that small number of members of the medical profession who were now acting in violation of the federal or state narcotic laws. Reviewing its work on venereal disease control, the Council recommended the adoption of the following resolution submitted by Surgeon General Hugh H. Cummings: "Resolved, That the venereal disease control movement cannot reach full effectiveness without the intelligent and sympathetic cooperation of the medical profession, and that this cooperation should include the rapid extension of teaching facilities for the use of medical students whereby the knowledge of the medical, social and public health aspects of these diseases may be taught by actual clinical contact with patients in the clinic, under the direction of qualified teachers." At the New Orleans meeting the Council on Health and Public Instruction was instructed to investigate the relative adequacy of the medical service and the relation of the public to the profession and to report at the next annual meeting. Several conferences had been held on which authorities on this subject were in attendance. After considerable discussion they formulated the statement published in the *Journal* of December 4, 1920, stating that they believed it desirable that the nature and transmission of communicable diseases be taught in the public schools, and that the teachers in the public schools should know something about communicable diseases. The Council was also of the opinion that there should be closer cooperation between the medical profession and laymen who were interested in public health, and the Council recommended that sections of public health and sanitation be organized in state and local medical societies, and that laymen be admitted to these sections as associate members. It was the opinion of the Council that the American Medical Association should, as soon as possible, begin the publication of a popular up-to-date journal on sanitation and epidemiology. It was the wish of the Council that this matter be referred to the trustees. The Council believed the American Medical Association should take steps to secure the following results: (1) To assist local medical practitioners by supplying them with proper diagnostic facilities. (2) To provide for residents of rural districts and all others who could not otherwise secure such benefits adequate, scientific medical treatment, hospital facilities and nursing care. (3) To provide more efficiently for the maintenance of health in rural districts. (4) To provide for young physicians who wish to go to rural districts, opportunities for laboratory aid in diagnosis. (5) The Council believed that this could best be secured by providing in each rural community a hospital with roentgen ray and laboratory facilities to be used by legally qualified physicians of the community. The attitude of the profession toward sectarianism was discussed in the report and the recommendation was made that the Council be instructed to appoint a committee to study the entire question of sects in medicine and the attitude which the American Medical Association should adopt regarding them and to report at a future session. The Council also requested that it be authorized to appoint a committee to survey the entire subject of vaccination against smallpox and to prepare suitable material for educating the public on this question. The Council also requested the House of Delegates to authorize it to call a conference in Chicago, probably in July to which should be invited the general officers of the American Medical Association, the presidents and secretaries of the state, county and local medical societies, the presidents and secretaries of various state and national public health organizations, and the health officers of the various States for the discussion of the present

state of public health work and for the organization of a plan for public health work. This report also included a review of state laws authorizing county and city hospitals and the text of the Iowa law for county public hospitals, as well as the text of the Michigan law for teaching disease prevention in the public schools.

Report of the Council on Medical Education and Hospitals.—Dr. ARTHUR DEAN BEVAN of Chicago presented this report, which stated that the task begun in 1905 of securing uniform and acceptable standards of medical education had in large part been completed. The accepted American standard was two years pre-medical work in an approved college university, a four years' medical curriculum and a year's internship in a hospital, forming as high a standard of medical requirements as that adopted by any other country. The work of the Council had grown to include a study of the problems of preliminary education; the undergraduate medical curriculum; the hospital in its relation to clinical teaching and the interne year; a graduate medical education and provision for the training of specialists; the development of the so-called group practice and the extent to which medical practice was done in hospitals. It was clear that the purpose of all this work was to provide for the public the best possible facilities offered by modern scientific medicine for the diagnosis, cure and prevention of disease. The people of our country, rich and poor alike, were entitled to the great benefits of modern medicine and some plan should be devised to secure these for them. There had been much discussion concerning compulsory health insurance and state medicine. As their knowledge of the situation had grown it had become more and more evident that these medical problems must be solved and the medical work done by the medical profession itself. In our democratic form of government the medical functions of the city, of the state and of the nation must be carried on by those best qualified to do it—the medical profession themselves. The medical profession must be awake to its greater opportunities and responsibilities, which meant the organization of the profession for further developing the practice of modern medicine. To accomplish this it was not necessary to build up a huge political machine. It was not necessary to alter in any way our present laws or our present organization. The organized profession should simply recognize the fact that its most important function was to secure for the public the benefits of modern medical practice and to develop intelligent practical plans to furnish the best medical service possible in each community. This plan means a cooperation of the profession with the municipal, state and national authorities. It meant an intelligent and energetic propaganda for the education of the people and the profession. It meant the creation of public opinion which would demand an efficient, sound universal medical practice and it meant providing the essential equipment. To-day it required an extensive public health organization to secure the benefits of preventive medicine. The development of this complex scheme had brought out the necessity of educating two classes of medical men, the general practitioner and the specialist. The general practitioner would always remain the most important single factor in the practice of medicine. The profession should recognize this and realize that the most important function of our medical schools was to train well qualified general practitioners and that the undergraduate medical course should be planned with that in mind. The time had come when we must reorganize our course of medical study so as to give a broader and less specializing training to the men who graduated in medicine, and who were to become general practitioners. The training of specialists should come later, such special preparation to be given to a limited number of men—10 per cent. or more of the practitioners of the community—who were to provide expert medical service in limited fields of practice. Too often the medical faculties do not include teachers broadly trained in general medicine and general surgery. The undergraduate medical course should be reorganized in several ways. The students should begin clinical work much earlier in his course. The anat-

omy and physiology and pathology and pharmacology taught should be the portions of these sciences which will be of service to the student in his clinical work. Anatomy and physiology should not be completed at the end of the second year but should be carried into the hospital and clinic. The clinical work of ten or more special departments should be simplified and given by the three departments, general medicine, general surgery and obstetrics. Whatever work was given in the medical and surgical specialties should be limited to the work required by the student as a general practitioner. The place for the specialist in medical education was in a graduate medical course and his function was the training of specialists. Dr. Bevan then spoke more at length of the advantages of general practice and of the dangers of a too narrow specialization. He said there were two safe plans for the practice of a specialist, first, by one who had obtained a broad view of medicine as well as the special training required in his limited field; second, by a specialist who, though he lacked the broad training of the general practitioner, acted as a member of a group well organized for group practice, so that patients referred to him had first been examined by one broadly trained in general medicine, who acted as the captain of the group, made a diagnosis of the general condition of the patients; decided what patients required the service of this or that particular specialist, and who controlled in a general way the diagnosis and therapy of the case. Some such general control was necessary in the safer practice of any specialty. The Council on Medical Education recommended that the American Medical Association undertake the further organization of the medical profession in this country so as to provide the benefits of modern medicine for all our people. The Council on Medical Education presented a statistical report showing the successes and failures of graduates of medical colleges at state board examinations.

The chairman then presented a comprehensive statistical report showing the results of state board examinations. He said that the table showed the results for all candidates who took examinations in 1920, regardless of the years in which they graduated. This showed that altogether 4787 candidates were examined last year, as compared with 4736 in 1919, 3637 in 1918, 4730 in 1917, and 4850 in 1916. This year shows an increase of 51 since last year and 1150 since 1918. Previous to 1919 there had been a steady decrease since 1906 owing chiefly to (a) the larger registration through reciprocity, and (b) the general diminution in the number of medical colleges, students and graduates. The marked decrease in 1918 was due to the enlistment of many physicians for military medical service. Of those examined in 1920, 15.3 per cent. failed, as compared with 13.3 in 1918, 14.1 per cent. in 1917 and 15 per cent. in 1916. There were 78 medical colleges in the United States granting degrees in 1920, which had graduates examined as compared with 79 in 1919, 80 in 1918 and 89 in 1917. There has been a decrease of 75 since 1905, when graduates from 153 medical colleges were examined. The statistics covering schools which have ceased to exist are included in the line for "miscellaneous colleges." Graduates of Canadian schools were examined in 21 states. The largest number, 31, were examined in New York, the next largest number being 10 examined in Massachusetts. Foreign graduates were examined in 24 states, the total examined being 86, and of this number 33, or 38.4 per cent., failed. In 1918, 45, and in 1919, 67 foreign graduates were examined. The largest number of foreigners examined in any state in 1920 was 19 in California, where 8, or 42.1 per cent., failed. Holders of certificates from the National Board of Medical Examiners will be registered without further examination in the following twenty states: Alabama, Colorado, Delaware, Florida, Georgia, Idaho, Iowa, Kentucky, Maryland, Minnesota, Nebraska, New Hampshire, New Jersey, North Carolina, North Dakota, Pennsylvania, Rhode Island, South Carolina, Vermont, Virginia. A holder of the National Board certificate is eligible for the regular medical corps of the United States Army or the United States Navy without further professional ex-

amination if a review of his examination papers by the board of examiners of those services is satisfactory. During the summer of 1920 several English and French physicians, as guests of the National Board, visited a number of the medical schools and attended the examination held by the board in Philadelphia in May, 1920. Since that time a recommendation had been adopted by the Triple Qualification Board of Scotland providing that holders of the National Board certificate be admitted to the final examination of that board. In January, 1921, action was taken by the Conjoint Examining Board of England. From the point of view of the prospective student who might be selecting a medical college, the facts regarding the standing of medical colleges were of extreme importance. There were 63 medical colleges now having complete recognition in all States. There were 7 others for which the few instances of nonrecognition were due to certain technicalities in State Board requirements. If the student got his medical training in one of the remaining 18 colleges, he would find on graduation that his diploma was not recognized in from 5 to 44 States!

The Council on Health and Public Instruction also submitted statistics regarding 6,152 hospitals, sanatoriums and related institutions in the United States. The figures were based on the reports of superintendents, directors, or other executives of the hospitals, or of the government hospitals, from the officers who are in a position to give the facts. Altogether there were 2,926 hospitals having more than twenty-five beds each, with a total of 293,825 beds, of which 196,535 on the average were occupied each day. There were 1,087 hospitals having less than twenty-five beds each, with a total capacity of 17,334 beds, of which 9,489 on the average were occupied each day. This made a grand total of 4,013 hospitals, the total capacity of which was 311,159 beds, and of these it was estimated that 206,024 were occupied each day on the average. Of the 4,013 hospitals, 3,219 reported a daily average of 166,060 beds occupied, and from the percentage of beds occupied in each State the total daily average of beds in the other hospitals of the State was calculated. On this basis, therefore, in the 4,013 hospitals, 206,024, or 67 per cent., of the beds on the average were occupied. The largest proportion of beds occupied was 76 per cent. in California, followed by 73 per cent. each in Connecticut and in the District of Columbia; 72 per cent. in Colorado, and 71 per cent. in Maryland. The smallest proportion of beds occupied on the average was 48 per cent. each in Arkansas and Nevada, and 49 per cent. in Alabama. A study of the proportion of beds to population in the various states was interesting. For the entire country the proportion was one bed to every 340 people. The State having the largest supply of hospital beds was Nevada, where there was one bed for every 139 people, followed by the District of Columbia, one bed for every 165 people; New York, one to 185; Arizona, one to 196, and Colorado, with one to every 198. The State having the lowest supply of hospital beds was Mississippi, where there was only one bed for every 1,054 people, followed by Oklahoma with one bed for every 980 people; Georgia, one to every 897, and South Carolina, with one to every 881 people. Although New York had 371 hospitals, it had a smaller bed supply in proportion to population than Nevada, which had only nineteen. Of the 3,027 counties in the forty-eight States, 1,695, or 56 per cent., had no hospitals. If it were not for hospitals of less than twenty-five beds there would be 330 more counties without hospitals. The ratio of hospitals to square miles ranged from 1 hospital to every 42 square miles in Massachusetts to 1 to every 5,780 square miles in Nevada. The ratio of beds to population ranges from one bed to every 139 people in Nevada to one to every 1,054 people in Mississippi; the average percentage of beds in constant use varies from 48 per cent. in Arkansas to 76 per cent. in California. As to counties which have no hospitals, Connecticut and New Hampshire were the only States in which every county had one or more hospitals, while at the other extreme comes Georgia, where 81.6 per cent. of its counties are without hospitals. It was noteworthy, however, that Georgia had 152 counties with an average of 386 square miles each as compared, for example, with 86 counties

in Minnesota with an average of 940 square miles each. A district most lacking in hospital supply was that represented by the South-Central group of States, which had only one bed to every 705 people, and 73.8 per cent. of the counties in the district were without hospitals. Only 61 per cent. of the beds in existing hospitals were occupied on the average. The fact that so large a proportion of the counties were without hospitals indicated that the hospitals were not well distributed. Mississippi stood out most prominently as the State most lacking in hospital facilities, there being only one bed to every 1,054 people; and 73.8 per cent. of its counties were without hospitals. The district which seemed to have the most adequate hospital supply was represented by the Western States, where there was one bed for every 211 people. This supply, however, was more apparent than real, since, on the average, 69 per cent. of its counties were without hospitals. The district which in reality had the most adequate hospital supply was that represented by the North Atlantic group, which had one bed for every 242 people; only 67 per cent. of all beds were occupied on the average, and only 15 per cent. of the counties were without hospitals. The States which had a well distributed hospital service were Connecticut and New Hampshire. In New Hampshire only 60 per cent. of the hospital beds on the average were occupied. Statistics were also given for tuberculosis hospitals, hospitals for nervous and mental diseases, Government hospitals, Public Health Service hospitals, Indian hospitals and Military hospitals. Altogether there were in the United States 6,152 hospitals, sanatoriums and homes, having a total of 817,000 beds, with the population of the United States according to the 1920 census as 105,683,108; there was, therefore counting all institutions, one bed for every 129 people. Dr. Bevan said there was one matter he hesitated to speak of, but which he had been studying for the past ten years. This was the matter of outside interference with medical education which he felt should be frankly resented and some definite action taken as it was becoming a menace to medical progress. He said he referred to the scheme of organization of medical faculties introduced by great foundations, and which had also been adopted by some of the State universities—the all-time clinical instructor. The plan did not originate in the medical profession but outside and had been forced upon them; it was a subsidized plan. It had been presented to the universities and they had been given one or two million dollars provided they would adopt a full time clinical plan. The originators claimed that this was an experiment, but if it was an experiment it needed a control. That was if three medical universities were conducted on the full time clinical plan and three others on the plan that was the product of the experience of medical educators, and a comparison of results made, it would be a better experiment. The full time plan had been introduced into Johns Hopkins, Yale, St. Louis, and a few other universities and into some of the State universities. It had not been a success. He did not hesitate to say it had been a failure. It did not have the support of the medical profession and he had not found that it had the support of the great teachers of medicine and surgery or of the great teachers of the medical and surgical specialties. It was a very expensive plan, out of all proportion to the results obtained in medical education. He thought the time had come when they should analyze the plans for teaching clinical medicine with the idea of trying to find the best one and adopting that. According to the full time plan, if a professor did consultation work the fees went not to the individual who did the work but to the institution. Thus the institution went into the practice of medicine. When a university did this it went into competition with the medical men of the State in the practice of medicine. The plan was not sound; it was not logical. It was time that the medical profession took the stand that it was not sound and not logical. While he had nothing against those who had introduced the innovation he believed the time had come to analyze the situation.

New Business.—The following resolutions were offered:

Dr. EDEN V. DELPHEY of New York introduced a resolution which read as follows:

"Resolved, That the American Medical Association is emphatically opposed to "State medicine," and to any scheme for "health centers," "group medicine," and to "diagnostic clinics," either wholly or partly controlled, operated or subsidized by the State or National Government."

Delegates from Illinois and Michigan introduced similar resolutions. That from Illinois also included public health insurance in the general condemnation.

A resolution was introduced requesting the American Medical Association to establish a Section on Anesthesia.

Dr. W. W. KEEN introduced a resolution, which was read by a Pennsylvania delegate, stating that he had visited the devastated areas of France and that the only work being done was that of the Committee for the Devastated Area of France and the tuberculosis work of the Rockefeller Foundation. Dr. Keen expressed his conviction of the value of the work and requested the American Medical Association to go on record as encouraging this work.

Another resolution urged the adoption of the metric system and the Centigrade scale by the medical profession in this country.

Dr. A. T. McCORMACK introduced a resolution in behalf of the Conference of State and Provincial Health Authorities of North America—urging that "the organized medical profession shall accept its responsibility for progress in the prevention of ill health and its causes, and shall support, through county and municipal medical societies, such diagnostic teaching and other clinics as will bring to all the people, whether living in the cities or in the country, all of the knowledge and means necessary to enable the members of every community, however remote from medical centers, to live through the years of their natural expectation with the utmost possible freedom from preventable and remediable disease and defects."

A resolution was introduced protesting against the high tax on alcoholic liquors used for medicinal purposes as an unjust burden imposed on the sick and mostly on the sick poor. The resolutions urged that the American Medical Association ask Congress to abolish the special tax on ethyl alcohol for use for medicinal purposes.

Dr. Frederic E. Sondern of New York introduced resolutions asking the Association to endorse a plan providing for the indemnity insurance in connection with malpractice defense. He explained that when under the compensation laws a decision was made against a physician there was nothing that could repair the damage to his reputation even though the financial claim was settled. There were no insurance companies carrying this form of indemnity. This plan would be operative under the malpractice defense. It would be optional and would be under the control and direction of the legal counsel of the various county and State societies.

The Cadduceus Post of the American Legion submitted a resolution calling attention to the advantages of universal military training for the young men of America and requesting the Association to go on record as favoring a plan for such training. A number of resolutions were introduced embodying the recommendations made in the various reports.

Second Day—Tuesday, June 7, 1921.

THE SPEAKER, DR. DWIGHT H. MURRAY OF SYRACUSE, IN THE CHAIR.

Memorial to President Harding.—Dr. HUBERT WORK offered a memorial to President Harding, which will be acted upon later. It expressed the American Medical Association's appreciation of President Harding's attitude toward the public welfare, through the educational advancement of public health administration, social security, soldier rehabilitation, child protection, and Americanization, and it assured the President of the loyal support of his policy for the correlation of the activities mentioned.

Fund for Graduate Teaching.—Dr. WORK also offered a resolution authorizing the trustees of the American Medical Association to set apart \$100,000 for graduate teaching and asking that "Foundations" interested in medical progress be requested to supplement this fund with \$100,000 for the same purpose. State societies

were asked to contribute \$50,000 toward the same fund. This fund is to be employed, directed, and administered by the trustees of the American Medical Association in conjunction with representatives of the foundations joining it, through a full time paid secretary.

Resolutions Opposing State Medicine.—Additional resolutions opposing State medicine were submitted by the Medical Society of the State of New Hampshire. These resolutions were as follows: "Resolved, that the Medical Society of the State of New Hampshire is emphatically opposed to 'State medicine' and to any scheme for 'health centers,' 'group medicine,' and to 'diagnostic clinics,' either wholly or partly controlled, operated, or subsidized by the State or national government; and that the delegates from this society to the American Medical Association be and hereby are instructed to present this resolution to the House of Delegates of the American Medical Association at its coming meeting in June and to use every possible means to secure its adoption." While a great many approved of this and the similar resolutions which had been submitted to the House, as they lay along the line of general opposition to such measures as health insurance and other forms of State medical paternalism, some were uncertain as just how much might be included in this rejection of group medicine, or how much was to be included in the term "State medicine." Several resolutions were submitted and were pending in the House attempting to define State medicine.

Dr. W. S. RANKIN of Raleigh, N. C., offered a resolution which included under the name "State medicine" everything that the Government at present did for the preservation of public health. It was said that "State medicine" was "any practice or policy provided for in the Legislative act of a State which had to do with the prevention or treatment of diseases, so that, if the association adopted this definition and then adopted the definition against State medicine, it would practically take the State out of the field of health work."

Dr. EDEN V. DELPHEY of New York thought the term "State medicine" should be defined by this Association as "the practice of medicine in the State by physicians on a salary to the exclusion of all other and individual practice of medicine."

These resolutions were all referred to a committee to be reported upon at a session of the House of Delegates to be held on June 9.

Want a Dentist on Hospital Staff.—The National Dental Association sent a communication to the House of Delegates in the form of a resolution urging the support of the American Medical Association of the suggestion that standard hospitals should have a dentist on their staff, and that they should use the x-ray to determine whether there were any pus pockets in the teeth. This matter was referred to the Council on Medical Education and Hospitals.

Popularization of Preventive Medicine Approved.—Dr. FREDERIC E. SONDERN, Chairman of the reference committee to which the recommendations looking to the popularization of preventive medicine and cooperation with the United States Public Health Service were referred approved these resolutions. The committee made the proposition that inasmuch as the Public Health Service was unable and some of the newspapers were unwilling to exploit subjects of controversy in the medical field, a Public Health Journal should be established that would be salable on the newsstands, holding its own in popularity with other periodicals. This matter was referred to the Board of Trustees.

A resolution recommending that all former presidents of the Association be seated in the House of Delegates was given favorable consideration.

The resolution requesting the establishment of a section on anesthesia did not meet with the approval of the House. A communication was received by the House asking for the appointment of a committee to study and determine the value of new appliances that were advertised. A resolution which was introduced favoring the closer cooperation between medicine and pharmacy to the enhancement of the dignity of the latter was approved and referred to the Council on Pharmacy and Chemistry for action.

OPENING MEETING.

June 7, 1921.

THE PRESIDENT, EX-SURGEON GENERAL WILLIAM C. BRAISTED, U. S. N., OF PHILADELPHIA, IN THE CHAIR.

THE Seventy-second meeting of the American Medical Association was called to order by the President, Rear Admiral William C. Braisted.

Invocation.—The Reverend GEORGE A. GORDON of Boston opened the meeting with prayer.

Address of Welcome.—HON. CHANNING H. COX, Governor of Massachusetts, delivered this address of welcome in which he said that among the worthiest citizens of Massachusetts were the 6,000 men and women licensed to practise medicine in the State. For the layman it would seem impossible to bring real success unless such a man were of rugged honesty, sterling character, and the highest ideals. Massachusetts had enjoyed having thousands of physicians who had been successful and who had contributed in generous measure to the welfare of mankind. If the services of the physician were tinged by selfishness his usefulness would be impaired. Governor Cox said he had asked a physician some time since to tell him the largest income that a physician was making in Boston. He was sure the figure given him was exceeded by the income of many lawyers, engineers and men of other professions, and by that of many business men. The physician did not count his reward in dollars and cents even in this day when so great stress was placed on material recompense. He stood ready to render service without hope of reward and to give his skill for suffering humanity. Massachusetts appreciated her physicians, and was justly proud of those who had lived and worked here and made tremendous contributions to the science of medicine. She encouraged her young men who wished to study medicine and she gloried in her splendid medical schools and hospitals. She felt indebted for the contributions physicians had made to the history of Massachusetts and because of what they were doing today. She was proud to welcome their brother physicians. She realized that progress in medicine and surgery redounded to the good of mankind. She felt every confidence that the deliberations of the scientific meeting would be a benefit to the people. There was a tendency of people to congregate in cities and this was becoming a serious problem. They had come to recognize that this overcrowding was a problem which concerned physicians. The medical schools today were increasing their standards and in larger numbers were graduating specialists and these young men were not willing to locate in the country where they lacked hospital and nursing facilities with which to do their work. Quite recently a beautiful Massachusetts town advertised that it would pay a subsidy to a doctor if he would locate in it. How this problem was to be solved remained to be seen, whether medical schools should lower their standards and send out admittedly inferior men, whether we should have State medicine, or whether we should have county hospitals in rural districts which would provide proper facilities for the young men to practise modern medicine remained to be seen. Whatever the solution would ultimately be the public looked to the medical profession for leadership. Massachusetts welcomed members of the American Medical Association not only as physicians but as representative citizens from other States and as men who were thinkers and capable of shaping the views of the public. Governor Cox said the Association had come on the three hundredth anniversary of the landing of the Pilgrim fathers and he hoped they had the same faith in themselves and their fellow men as the Pilgrim fathers had, and believed that it was better for the individual to do the thing he was fitted to do rather than to have the State do it for him. He hoped that after the work here they might return to their homes convinced that they had kept the faith of their fathers and believed that there was as great an opportunity for everyone now as at any time in the past and that they would stand ready at any time to defend the free institutions of America.

Address of Welcome.—HON. ANDREW PETERS, Mayor of Boston, delivered this address. He said it was indeed a pleasure to welcome the American Medical Association to Boston in the name of its citizens. He was here to speak for 800,000 patients, the whole population of Boston bid them welcome and godspeed and appreciated all that the physicians had done for them. They had helped bring them into the world; they had helped to make life a pleasure and they were here to acknowledge their indebtedness and to express their appreciation and deep gratitude. From the memorable day when Dr. Joseph Warren refused the command of the troops and chose to serve and meet death in a private capacity for his country, from that day down to today the physician had brought with him that high ideal of service to the community. The medical profession had stood in Boston in a position unequalled in any other city in our country. They had in Boston many institutions which helped to further their health but these he would not describe as there were better guides than he at hand who would point with pride and particular knowledge to these institutions. There were Dr. Woodward, Dr. Dowling and Dr. Minor who would be ready to point to their municipal hospitals and public health hospitals and show how they had spent \$4,000,000 in the health of the city. There was one subject which even a layman might touch upon. Their health department was busy preparing to keep out the bubonic plague. He was interested in stopping another danger which had just swept away 10,000,000 people in Europe. It took diabolically the young and the strong and it ruined the best stock of future generations. We were told we must prepare for a like scourge in the future by those teachers of discord who were urging it. The old code of chivalry was being pushed aside and we were told that the object of the next war would be total extermination with no regard to the weak or the helpless. What was to be done to forestall this catastrophe? He suggested that the Association protest against it as their work was directly opposed to such a destruction of life. Ninety-nine men out of every one hundred were opposed to it and every woman would support such a protest. Boston would be proud if she could add to that other great medical event, the discovery of the use of ether as an anesthetic, the fact that the medical profession had taken here the first step to bring mankind back to sanity, good will and common sense. They had a monument to Dr. Morton, he wished they could have a peace monument to the American Medical Association. They would be welcomed by special hosts the pick of that chosen profession of which they were members. They would show them the opportunities that were here for increasing the medical service of the people who were giving up their lives to medicine, and were being inspired to high ideals and progress.

Dr. WILLIAM C. BRAISTED, in introducing the president-elect, said that the next speaker needed no introduction before this Association from him. He was a man who had done as much as any and few had had as much experience in the work of the Association. His opinion was looked up to with respect and his advice was generally taken. He confronted a year which was one of the most important years in the history of the Association. There were many problems before the Association to be solved today both for itself and for the welfare of the people. He needed all the support and all the help that the Association could give him. He took pleasure in introducing President-elect Hubert Work.

President's Address.—Dr. HUBERT WORK of Pueblo, Colo., delivered this address, taking as his title "Some Medical Problems." He said that the watchword of the American medical profession should be "service." There was no point of view from which we might together look out on the future except that of a united interest. Community necessities, touched by a spiritual vision fused the beacon light of the Pilgrims who founded this nation. Community interest had developed every pioneer town since they landed on this historic site. It had built our public schools, preserved the unity of our States, and, recently, saved our nation to us. It was this primitive spirit, inherited from those heroes of want, easy to coordinate and effective beyond resistance, that was still the moving motive of this nation. These

*Abstracted from advance sheets through the courtesy of the editor of the *Journal of the American Medical Association*.

people perfected the higher human attributes through physical hardships to which we are strangers. Under spiritual guidance they were refined. They made us what we are by transmitting to us the spirit of hope and the imagery of conquest. They, and their kinsmen coming after them, were the hereditary legates of independent thought and high aspiration. Self-governed by their religious traditions, they lived from within outward: worshiped the spiritman, and anchored themselves to eternal principles. They fought for peace; thrived on privation; triumphed over self and lived for each other, until each for himself set out on the lost trail alone and unafraid.

The American Medical Association, Dr. Work said, was a body representing more than 80,000 trained medical men. It was the Plymouth Rock of American medicine, and we might look back through its history, and therein trace the evolution of the healing art. It was our national health service, and the common meeting ground of its members. The governing purpose of this association was to collect and disseminate the truth in medicine, to perfect the science, to expose pretense, and to elevate medical men, to encourage and associate individual efforts, and to bind medicine to the government, its armies and its municipalities. And it hoped that the church and public charities, through the common tie of human sympathy—the hall mark of a Christian civilization—might also join with it for the greatest good to the greatest number.

The physician had a duty to those who called him. As a citizen he had a community obligation, and, through organization, an opportunity to serve, second only to that of the national government. But he must first identify himself with the interests of his community, living with his people rather than on them, that he might know their minds and sense their necessities. Only recently, when civilization's superstructure was being rocked by war, the world had its first opportunity to evaluate, in a crisis, the quality of physicians. One half of the medical men of the United States were promptly in uniform, in community war service or pledged to war's exigencies. The other half staggered, but stood up, under multiplied burdens at home. Our nation will not again follow its prewar social, professional or business customs exactly. New opportunities have presented themselves, requiring different methods of approach. Thoughtful men believe that now a crisis threatens established principles, and that physicians must earnestly address themselves to the cause and the prevention of disease and disability as the primary concept of medicine, safeguarding its principles, lest the profession lose its esprit de corps, and its place in public esteem.

Our people regard medicine in a new light, as a virile, organized force, quite independent of the sick chamber or hospital environment. They now urge that it must include the larger field of civic service for those who are well. When pestilence invades our ports from abroad, the first appeal of a terrified people is to the United States Public Health Service. When an army is to be mobilized "over night," the Medical Corps of that army must reject the unfit, isolate those infected before induction, and vaccinate against diseases of contact, while the Medical Corps of the Navy protects those at sea. No one now believes that medical practice is limited to prescribing drugs. The art and science of medicine is comprehensive and rational. It can never be dogmatized or restricted, for it comprehends a knowledge of every art and science which may contribute to it, for the single purpose of obviating the tendency to death. No one now believes that the physician should husband his special knowledge and sell it to individuals only; medicine is recognized as a public service, and we must contribute our quota to the public welfare because we are citizens set apart as servants of health.

There is uncertainty in the minds of thoughtless people as to the difference between physicians and pretenders, a confusion due to the fact that many diseases are self-limited regardless of treatment applied. Many that are sick recover quite independently of the kind of treatment, or in the absence of medical advice.

When recovery occurs under the ministrations of those ignorant of anatomy, physiology or pathology, it is regarded as a phenomenon. If under the care of a

trained physician, it is regarded as the logical result. The attitude of a physician toward disease is to prevent it if possible; or, failing this, to aid Nature in the contest against it, by simple measures if he can, or by radical means if he must. The most intelligent, educated effort is necessary to either. The attitude of the quack is not to prevent disease but to invent it; to entertain the patient with promises of a cure he cannot give for a disease he cannot diagnose. Physicians are indifferent to quackery as a competitor in all its phases. Their only interest in medical licensure is to prevent appropriation of the title Doctor of Medicine for the purposes of deception. The organized medical profession does not attempt to control, nor does it care what a practitioner prescribes, provided he has learned what the human body is, through his knowledge of anatomy; what it does right in health, through his study of physiology; and what it does wrong in disease, through his training in pathology.

The Young Man in Medicine.—Our young men are being graduated, standardized, and classified scientifically, much as the finest steel is fashioned. What may be done to develop their interest in the province of medicine, and to insure their identification with the demands of their respective communities, is an immediate responsibility of the organized profession. The young man in medicine may be assured that its future offers to him something no other vocation has to give; the always open door to recurring opportunity. But he must not enter the domain of medicine with the commercial instinct, or he will not learn to interpret it. He may master its words and quote its forms of speech, but the language of medicine is the signal of the human heart for help, which only the true physician can interpret. Years ago the general practitioner conceived his duty to be that of a healer only. He regarded disease as inevitable, if not indeed providential. Later he advised his clientele how to avoid it. Both of these functions he continues to exercise; but a new field presents itself; medical men must now combat disease in the mass; and disease includes wear as well as infection and its sequelae. Neither individual preventive nor curative service is minimized by this new perspective, but rather each is intensified. Those trained as bacteriologists, protozoologists, biochemists and physicists are rapidly increasing in numbers. They are men who may never see the patient, but whose services are necessary for the timely recognition of a disease before it gets out of hand.

The public has demanded that medical education be extended, until it now requires for its intelligent application scientists who are familiar with its most abstruse problems, having the vision of statesmen, the tact of politicians, a mastery of the sciences, and technical training. These qualities are obtainable only through the collaboration of many minds. All this means greatly diversified duties, and calls for more specially trained men, meanwhile amplifying opportunities for younger men in medicine and compelling their dependence on one another. This situation has developed the need among medical men for a type of practitioner who can group and weigh all symptoms essential to a diagnosis: only a new description, perhaps, of the family physician, but one tremendously broader which we fondly hope the internist may fill.

The Future.—The needs of mankind have created and developed the physician, but we now have progressed in the curative art as applied to the relief of a single organ as far as we may safely go without advancing a philosophy of medicine applicable to a nation. Medicine has not become too technical; but its application to the material man is absorbing, and has of late been tremendously stimulated by the postwar slogan of vocational training for productive education.

There is so much more to a human being than a test tube or a cadaver or an animal can disclose that we dare not neglect his distinctive attributes. If food and clothing were the only human needs, our young men might well be taught to obtain these in the most direct and primitive way. If the things of the spirit, which the cultivated crave, are to be nurtured, we cannot separate or subdivide medical education into segments, restrict its limits, ignore the refinements of science, detach a specialty from the body of its parent, or divorce medicine from other sciences and arts, and ex-

pect it to stand in its proper place. The practice of medicine dominates some men to the exclusion of many things that broaden and sweeten life. To boast of no knowledge outside a specialty, to smother interest in cultural arts or collateral sciences, to ignore the spiritual distinction between men and animals, is to invite professional deterioration and exclusion from the highest concepts of the profession.

There is no science, art or material substance which cannot be made to touch, contribute to, or blend into the substructure of this vital science of human life. Medicine may be likened to a tree. The sciences are its roots, organization is its trunk, its practitioners are its branches, and the people are its leaves. The leaves must fall when their season wanes, but the roots are indestructible. The trunk is sturdy, but the branches must be pruned to insure maturity for the human foliage. There is a tendency among medical men to limit themselves to diagnosis, to the neglect of preventive and therapeutic measures. Nothing gives so much reassurance in sickness as a prompt diagnosis, for it is the first essential to treatment; but immediately a prognosis, adequate therapeutics and protection against recurrence of the ailment are sought.

Graduate Teaching.—Continuance of the present high plane of medicine is contingent upon the development of graduate work. The profession has been delayed for want of it, and it is being hindered by some proprietary graduate schools, precisely as the profession was depreciated by inferior, faculty-owned, undergraduate schools, now practically past. Graduate training of physicians should mean more than the teaching of methods of diagnosis or operative maneuver by a specialist, however eminent. It should include the problems of living; the physician's relations to his environment; his duty to it and responsibilities for it; his contact with practitioners of similar attainments and common interest—a medical exchange or a professional clearing house; for nothing dulls the edge of competitive suspicion as does association for a common purpose, and nothing of importance can be accomplished by us comparable to the teaching of the practitioner in order that the public may be taught.

The first and last hope of scientific medicine lies in the medical colleges, and with the local medical societies. Nothing needs to be done for teaching centers by this association other than has already been done, except to encourage the highest standard possible to each one. If each component county medical society would strive to learn how much it could give to the profession rather than how much it could extract through it, with the unwholesome competition that this attitude compels, then the agitation for compulsory health insurance would pass, common centers for community service would arrive, charlatans perish, incomes be augmented, and professional security be advanced.

Colleges have learned to look longingly to the great foundations organized for higher medical education and for research in establishing scientific facts heretofore elusive, or at most conjectural. No one should criticize such appropriation and expenditure in itself; but, having in mind the medical discoveries and inventions of the last century made by physicians in villages, working alone, we may well wonder whether the ends in view would not be better served by application of the great incomes from these endowments to the encouragement of physicians in little villages, working from below upward for the relief of what is known, rather than in a search for what may not exist or possibly will prove of negligible value, if found. Suggestions that the standard of medical qualifications be lowered to men willing to practise in the country are unworthy. Offer a chance for professional advancement to the physician already there. Take to him the graduate opportunities he craves, and he will remain and serve well. Let the great foundations, the schools, and the American Medical Association unite to send teachers to physicians at their work, which they cannot leave. Ask the county medical societies to co-operate; then the public will recognize organized medicine as a going concern and will support its attempted philanthropies.

Health Centers.—There is need in every locality for health assurance, through improved health service. Health centers are in operation, for which communities

tax themselves, in order that their indigent sick may be treated. Other communities propose to institute like service, asking the State to share the expense. They may aid the physician tremendously in caring for the sick, by conserving his time, and supplying laboratories and aids not otherwise available. Such centers should lessen expenses to the ailing and stimulate medical accuracy, because under the supervision of several medical men. There is an opportunity through them for physicians to assume their rightful place as an organized influence for health betterment in every locality. This will be rather simple of accomplishment. We have constructed, and in place, the machinery to develop these things—the county medical society, under our national center. The plan of organization is perfect. All that is needed is to re-vivify the county medical society, to stimulate it through the State societies, and to enlist the public in our efforts to prevent disease and shorten sickness. Clearly the State, or some unit of government, should contribute to install at convenient points the housing and apparatus necessary to medical precision, making it available to the poorest; but beyond that an organized government should not go. The intimate relation between physician and patient must be preserved where it exists, and restored where lost, if we would give our best aid, and avoid a whole time State service, with its attendant commercializing of the profession of medicine, and the stressing of trade features. State governments, through their teaching universities, may not justly, for a fee, attract patients for medical treatment. It is the function of a teaching college to train physicians, and scatter them for public use, and to instruct, develop, and protect them as alumni in their several places. The duty of a medical college to its graduates does not end with commencement day; and certainly it is no part of that duty to divert patients from the graduates whom it has sent out with its seal, approving their qualifications for similar service. Instead, its duty is to assist them further in qualifying for their work. It cannot draw the sick to a common center for pay, in order to augment the salaries of its teachers, without breeding distrust, relieving citizens of their proper sense of responsibility to their neighbors, and incurring just antagonism of its alumni. The State must administer its assistance in public health matters, if at all, locally, through the taxpayers immediately interested. Physicians want neither personal help nor interference; but they do want the different units of government, under which they live, to do their plain duty in the contest the medical profession has waged against disease since the time of Galen.

Hospitalization is now the first thought of the sick, partly for professional, chiefly for economic reasons. The public regards the hospital as a public beneficence. The surgeon demands that the hospital shall be a suitable place in which to operate. The physician regards it as a necessary adjunct to the whole scheme of health. We would have the laity taught to see the hospital as a sociologic institution, a place of refuge accessible to the well for prophylactic advice, and to the sick for their unrestricted use instead of a retreat accessible only to those able to pay, operated primarily for profit and not available to all. By the same token, public hospitals must arise for those without accumulated means, who are not paupers, and the church should assume aftercare, in the effective dispensation of coordinated charities as sociologic institutions, with medicine as their adjunct. Modernized hospitals can no longer be maintained by fees alone, nor can a university, and for the same reasons. If the State may properly support universities for training the student, and maintain hospitals for the custodial care of its insane poor, or a county may levy a tax for the maintenance of its county farms, logically the State or county may assess itself in order to treat its ambulatory sick, and to provide equipment to keep in earning health its essential human economic factors.

Standardization.—The standardization of medical colleges upward has been accomplished largely by stimulating pride of occupation among physicians. The elevation of hospital service, to which the impossible term "standardization" has also been applied, is engaging the best minds in medicine. Both of these movements have been actuated by a desire to protect

the life of those made helpless by sickness. The one begins with qualifying physicians; the other undertakes to obtain for them a safe environment in which to do their work. Neither one, however, has assumed to protect the patient from the unqualified or the commercially graduated surgeon, the dishonest internist, or the criminal who operates for a fee, or who brings his victim to a hospital to die as a result of their joint unlawful act. In the standardization of medical colleges, our association dealt with educated professional men. Attempts at standardization of hospitals instantly were countered with the necessity for daily income, with lay vision, without medical prescience; having in mind the financial liabilities of their institutions, and the fear of losing the patronage of even the most unworthy practitioner. Ideal hospital standardization is far from realization because it is impossible. Minimum requirements only can be fixed before a hospital may be approved by some committee representing organized medicine. The elevation of the standard of surgeons who work in hospitals should have been coincident with these attempted betterments of facilities, for any hospital service is the shadow of those who work in it. Standardization of hospital staffs is simpler than that of either medical colleges or hospitals, and would in itself insure the latter. Permission to enter patients in a hospital should be notice to the world that physicians admitted there are qualified and trustworthy men. The courage of conviction, weighing human life in the balance with the qualifications of those seeking to be trusted with it, is the simple requirement for hospital staff standardization, and should control all hospital managers. Hospital service should mean to the world that those admitted to it have been approved by an impersonal, national licensing board, similar to our national examining board, whose disapproval might not legally interdict access to hospitals, but whose approval would become an unqualified assurance of uprightness of purpose, at least, with a modicum of medical qualifications.

Group Practice.—The grouping of physicians for the private practice of medicine is an expression of community need, but it is easily directed to primarily selfish interests. It is a medical ideal for immediate intelligent service, protecting the interests of those served. Eventually, where financial features are involved the division of earnings and the distribution of patients, with the hiring of fellow physicians as assistants, may suggest that these services have been commercialized and the way be opened for criticism. Group practice means association of personnel, with segregated service. It conserves time and cultivates special skill. Apparently it is of scientific advantage to those engaged in it. It gives a broader service for a fixed fee than is possible from isolated practitioners. It does not insure great incomes to the members composing it; and it limits the development of initiative and the personal independence of the younger men attached to it. Group division of practice, which does not preclude the patient's option of selecting a consultant to members of the group, but recognizes equal skill in physicians not attached, and approves their employment, is ideal both from a professional and from a public point of view. Associated group practice, without a pooling of earnings, should receive public sanction; otherwise a danger pend, for money should come through medicine only from devotion to the vocation first, and from concern for its earnings afterward.

The Occult.—A curious cult which treats all illness as imaginary has arisen in this cultured city. It soothes the sick by denials, while nature effects a cure or the sufferer passes out, much as a mother assures her frightened child at night that its terrors are dreams and without substance, until realities readjust its disordered fancies. Although this theory of the "three Graces" is not applied to food or clothing or housing, admits birth but denies death, denies disease and ignores its causes, it has been a lasting comfort to those who are well and finds prepared soil in distress, for "in the shadow of a great affliction the soul is dumb." The Christian religion has been taught 2,000 years without recognizing in practice the basic principle of its founder, read in the challenge, "Show me your faith without your works, and I will show you my faith by my works." The human touch of a spiritual man

was the professional equipment of a physician the world has worshiped for twenty centuries. Yet His spiritual teachings have been passed to ministers of His gospel, and His miracles of healing have been emulated by doctors of medicine. As a people, our faith in help through prayer has preserved the tottering reason of millions, until nature has benumbed bereavement or relieved racking pain.

Lay Healing.—This is a legitimate field for lay practice, directly within the province of the Christian church and its ordained ministry, but not to be intrusted for a fee, to the ignorant, who sit stolidly by a passing life repeating false assurances by rote. We must learn to minister to a mind diseased: not alone to alienated faculties, but also to sensitized emotions and outraged affections. Ministers of religion and ministers of health must jointly associate the beneficence of faith with the beatitudes of work, that the whole man may be conserved, and their professions saved also. The joining of interest, through common channels, by those who would guard public morals, assure public health, and rehabilitate the poor, is the most inviting question of the moment and logically falls to medical men, who should enlist with them the ordained ministry for this world's work.

The Common Conscience.—Those having minds sensitized to impressions from without believe that the public conscience is undergoing an agitation that is new to our generation; that this is indirectly due to reaction in our code of social ethics and that we must now recognize the struggle between the forces of normal, stabilized mentality and those of the wavering deterioration of the subnormal. In this favored State the names and addresses of 12,000 feeble-minded people are known. A great authority on this subject estimates the number to be ten times that. The city is said to have seventy-seven rooms in its public schools devoted exclusively to backward children. From such as these come the criminal, the prostitute, and the insane—the socially impossible group of to-morrow. Their reproduction is unrestricted, and they are purveyors of disease; while in contrast, those higher in the social scale limit births, and struggle for health. Meanwhile the burden of the unfit grows heavier, and the moral plane of the nation is lowered. The sex appeal to arrested mentality is out of all proportion to the wholesome balance of a normal mind. The moving picture featuring sex instincts appeals to increasing numbers, resulting in multiplied illegitimate production. Each State has the same problem, and it is our problem. The legal profession cannot cope with it. True to training, it will be found arrayed, one half prosecuting, one half defending. The church cannot meet it, because only those choosing uprightness go there. The schools have already despaired, because the child is "not all there." Only the physician is in touch with this thing, and he knows the simple remedy needed to restore, by elimination, the higher intellectual balance necessary to national integrity. He recognizes these contending forces in race development and decay. He has many times voiced warnings of a parting of the social fabric, but the decline of a nation's mentality goes on, unheeded and unrestricted. Theoretically, we should expect our enfranchised women to rise against the moron rapist, or the possible introduction of the taint of feeble-mindedness into their lines of descent. Practically, the sentimentality of women secretly protests against limiting the so-called privileges of parentage. There are no rights of parenthood which should, through any process of reasoning, take precedence over the right of the child to be well born. Certain religious sects, believing that the soul is independent of its physical abode, are unwilling to interfere with its transmission, even through tainted, vicious, weak or criminal channels. It is not future wars between virile fighting men which we have to fear: it is the deterioration of the mind, and the inevitable loss of respect for our individual rights, our traditions, and our highest ideals, through a submerging mass-mentality.

In closing, the speaker said that American medicine had its greatest achievements before it. It must go to the crossroads and villages for its vision of service, call in its troopers, and train from the outskirts, toward common centers. It must prevent disease where possible, relieve it where it occurs, aid in the upkeep of

earning power, and contribute its influence to maintaining the integrity of a nation's physical and moral fabric. He would plead for the spirit of service which governed practitioners of the last century, who, knowing less of medicine, depended more on personal attention than we now do; for the spirit of William McClure, of fiction, confined for a life time to the highland limits of a day's ride; of our own General Gorgas, who converted a slough of death into a resort for health, and turned the traffic of a world; for that which prompted the self-sacrifice of Walter Reed, who invited death that others might safely pass; the spirit of thousands of men who have preceded us, whose names were unknown or have long been forgotten, but of each of whom the recording angel wrote, "He went about doing good."

SECTION ON MEDICINE.

First Day—Wednesday, June 8, 1921.

DR. HENRY S. PLUMMER OF ROCHESTER, MINN., IN THE CHAIR.

Tropical Sprue.—Dr. DAVID BOVAIRD of New York presented this paper in which he stated that tropical sprue in New York was an imported disease. Of 13 patients studied at the Presbyterian Hospital 12 had come from different parts of the Orient and one from Porto Rico. In the countries from which the disease came it occurred not only among occidentals but among the natives of those countries as well. The theories as to the causation of the disease were numerous, it being variously attributed to dietary errors, infections of different kinds and to yeasts. However, the definite etiology of the condition was still an open question. It was shown that the disease could be definitely differentiated from infantile sprue. In the cases coming under his observation no definite organism could be found. In one case only had the *Manilius albicans* been found. An exhaustive study of the intestinal bacteriology had been made in two cases by Dr. Hans Zinsser and Dr. Russell L. Cecil, but no important deviation was shown from the normal bacteriology of the intestinal tract. They had had but one autopsy with a bacteriological study of the tissues. In this instance a mucous enteritis was present involving practically the entire intestinal tract, and nothing more. The pathological study likewise gave no clear understanding of the disease. The symptoms of the disease were well known, consisting of a combination of sore mouth, diarrhea with one to four bulky, pale gray stools with much gas, secondary anemia and exhaustion. In the present state of our knowledge one had to recognize the disease on physical grounds alone. The abdomen was usually tympanitic. Protoscopic examination was made in nine of their thirteen cases and gave no characteristic picture, the appearance of the mucous membrane running all the way from a bright red in one case to a pale anemic appearance in others. A study of the gastric contents was made in twelve cases. Six of the twelve cases showed a total lack of free hydrochloric acid, while five gave practically normal findings. One case that gave normal findings in 1912, showed an absence of free hydrochloric acid, in 1919, at first but a gradual increase to 36 at the end of a three hour period. There were variations in the stools from time to time depending to a considerable degree upon the diet, exercise, and habits of the patient. It had been thought that the pale color of the stools might be due to an absence of bile pigments. The bile pigments, however, were not absent but were present in the form of colorless compounds. There seemed to be present an impairment of the power to absorb fat. Although there was excessive gas distention the ferment tests had given but indifferent results, probably due to imperfections in technique. In eight cases the hemoglobin was very low, in one instance being as low as 21 per cent, and suggested a hemolytic process but dissimilar to that of pernicious anemia. Various studies on the chemistry of the blood showed normal results. Study of the pancreatic ferments showed that trypsin was not regularly present without amylase nor vice versa. The urine presented nothing of importance in routine examinations. The calcium

in the blood was found to be somewhat below normal in some of the cases. The administration of calcium lactate, however, failed to make any change in the calcium content of the blood, and tetany developed in several instances. The Wassermann reaction was negative in all the cases. In the absence of any characteristic laboratory finding the diagnosis at the present time, therefore, rested upon the clinical picture. The treatment was dietetic, but the diets upon which patients had recovered presented a bewildering variety; in most instances they consisted largely of fruits. Of the fruits the strawberry seemed to be one of the most important but the benefit derived from it seemed to rest upon the fact that it restricted the food intake. To him the dietetic problem presented by a case of sprue was much like that presented by a case of difficult feeding in infancy. It was of particular importance that starches in the form of potato and bread be kept low. By regulating the diet in this way these patients had been enabled to carry on and most of them had recovered. The administration of pancreatic extracts had appeared to be beneficial in some cases and useless in others. Patients who had once suffered from the disease should not be permitted to return to the conditions under which the disease had developed.

Dr. JOSEPH PRATT of Boston said that the disease sprue was worthy of the attention of every practitioner in the country. Of course it was a very rare disease, but it was absolutely important and essential that if called upon to treat a case of sprue the physician should have some knowledge of the diagnosis and proper treatment of the disease. He recalled the first case referred to him accompanied with a letter from a physician in Porto Rico stating that the patient had sprue and asking that his diagnosis be confirmed. At that time he had no idea what sprue was. This was his first chemical as well as clinical study that gave him an insight as to what the disease was. There seemed to be disturbance in the metabolism affecting the absorption of fats and starches. He knew of cases of sprue which had come back from the Orient and the physicians who had treated them were quite ignorant both of a proper knowledge of the disease and the proper method of treatment. He felt that the heads of mission boards should organize a campaign of instruction for patients returned from the Orient with sprue telling them to whom they should go for treatment. Dr. Pratt called attention to the fact that some persons returned from the Orient who thought they were suffering from sprue simply had sprue phobia, or fear of the disease. Manson's original treatment of milk diet was an effective form of treatment. Santonin was used by some and particularly by the physicians in China. Manson's milk treatment was frequently not used in cases in which it would be of help.

Dr. THOMAS BROWN of Baltimore said he had been interested in this group of cases for some years. His experience, however, was limited to six cases, three from Porto Rico and three from the Philippines. He had been particularly interested in studying the pancreatic findings. In his cases there was an absence of pancreatic ferments both from the stools and the duodenal contents. In several cases a gastric achylia was present which with improvement returned to normal. There was acidosis in three of five cases. One showed no change as regarded acidity. Few studies had been made of the pancreas at autopsy probably because it degenerated so quickly after death. Castellani had come to the conclusion that grossly nothing was to be seen except the usual picture of chronic pancreatitis which statement was of very doubtful value without microscopical corroboration. He had had the same experience as Dr. Bovaird in failing to find the *Manilius albicans*. He knew of two or three patients from Manila who thought they were getting good results from the use of neosalvarsan; none were cured but they felt that they were benefited. The condition might be due to a variety of infections or it might be due to a lack of vitamins as suggested by some observers. In the treatment of very difficult cases it was well to consider all the factors dietetic, absence of ferments and other factors that might possibly be involved. In that way one might bring about an improvement though a perfect cure was rarely to be expected.

Dr. FREDERICK DE LUE of Boston believed we were getting rather unduly alarmed as regarded the admission of these cases into this country. He believed they occurred quite frequently here and were overlooked or regarded as cases of disturbed digestion which could cure themselves by going on a mild diet. It seemed to him rather suggestive that the disease was a tropical disease and that the greatest food of the tropical countries was fruit. He related an instance of a patient who had partaken of canned and preserved fruits that had been stored for a long period and developed a quite typical case of tropical sprue. He believed it was not a germ disease, but an acidosis and a reflex from irritation of the gastrointestinal tract—a marked type of catarrh of the gastrointestinal tract. Being an acidosis the treatment was skimmed milk with the administration of sodium bicarbonate.

Dr. BOVAIRD of New York, in closing the discussion, said that observations made on this disease before the section 1919 indicated that sprue did occur sporadically in this country. He recalled a case coming from New Hampshire. The disease was by no means confined to the city. A study of the pathology of the condition was that of atrophy from the tongue on through the gastrointestinal tract with a disruption of the digestive processes. It seemed evident that the great majority of cases were destined to recover whatever was done; some cases were fatal, however, in spite of the best that one could do. The rational dietetic treatment was skimmed milk because it imposed less strain on the digestive tract, but it could be maintained for only a brief time without the addition of other forms of food.

Studies in Familial Neurosyphilis.—Dr. JOSEPH E. MOORE and Dr. ALBERT KEIDEL of Baltimore presented this communication, which was based upon a study of fifty-two marital partners of fifty neurosyphilitic patients investigated by means of amnesia, physical examination, and study of the blood and spinal fluid. Of these forty, or 76.9 per cent., had syphilis; twenty-one, or 40.3 per cent., had neurosyphilis. Thus of the total syphilitic partners 52.5 per cent. had neurosyphilis. In the partners of parenchymatous neurosyphilitics the incidence of neurosyphilis was about twice as high as in partners of meningeovascular neurosyphilitics. After discussing the various types of neurosyphilis observed the writers spoke of the relation of infection of the partner to the duration of marriage and of syphilis in the syphiliphilic. If the original infection took place three years before marriage the marital partner was less likely to acquire neurosyphilis though he had seen cases in which neurosyphilis was manifested in the marital partner when the original infection was contracted five years before marriage. In general, however, the chance of acquiring a neurosyphilis was in proportion to the length of time between the original infection and marriage. The results of the observations were discussed in reference to the theory of duality of strain of *Treponema pallidum*. It was shown that the evidence was inconclusive as to the differentiation of a dual strain.

Dr. HENRY SALMON of Boston said he was much interested in the results of these observations, particularly as they ran higher in percentages than those he had investigated. They had published observations on 555 families of syphilitic patients, which were divided into the paretic and cerebrospinal groups, and a group in which the cerebrospinal system was not involved. While the percentages were lower than those just reported the result was more of a standard, as there was less chance of the individual equation interfering with the results. They found a positive Wassermann in from 23 to 35 per cent. of the cases, as compared with the 76 per cent. in the series just reported. They had not reported the spinal fluid findings as a routine, because it was impossible to do so in such a large group. However, in the cases in which the spinal fluid was examined the positive spinal fluids ran under 10 per cent. All of these had positive Wassermann reactions. In their group it was interesting to know that not more than 25 per cent. of the mates with neurosyphilis suspected that they had syphilis. They had gone through the hands of many physicians and the diagnosis had never been made. The same thing was true of the children in these families. The average at

which the diagnosis was made on the children was between ten and twelve years. He felt that this fact was very important from the practical standpoint. Most physicians were not interested in the families from the standpoint of syphilis when it had been five to thirty years since the original infection. If one considered the autopsy findings there was reason for being conservative in regard to duality of strain of the *Treponema pallidum*. The vast number of patients with neurosyphilis showed aortic and other involvement. The syphilitic organism at least had a predilection for the vascular system so that it could not be considered a pure nervous system strain.

Dr. JOHN H. STOKES of Rochester, Minn., asserted that in spite of their pronounced admiration of laboratory mode of attack he wanted to insist that the ultimate plane of reference must be the clinical. They had been told many things about neurosyphilis long before the laboratory methods had been worked out, though he could not deny that they had likewise been told many things that required modification. A second point he wished to bring out was the underlying principle that there were multiple agencies involved in the production of neurosyphilis. He classified these under four heads. 1. The strain of organism. 2. The duration of the infection; the picture might be entirely different five years after the infection in the subject of syphilis from what it was shortly after the time of infection. 3. The soil upon which the infection was implanted was increasingly coming to their attention as an important factor in determining what happened. 4. The final factor was treatment; this was very far from being definitely evaluated. Genierich had studied the effects of the so called modern method of treatment and he had faced about and felt that arsphenamine was dangerous and predisposed to neurosyphilis. The group working at Rochester had studied syphilitic pairs in which they were certain that the strain was the same and the duration was the same within a few months. In this study they had found many interesting things which were not at all conclusive. It was found that there was a definite tendency for men to develop neurosyphilis over women. The woman had many protective factors which the man did not have. One saw cases of severe cardiovascular syphilis and no neurosyphilis and at other times severe neurosyphilis and slight cardiovascular involvement. So he thought they needed a revision of their clinical knowledge of syphilis based upon the examination of the spinal fluid. Latent neurosyphilis had never been reckoned with in the past, and he believed the examination of the cerebrospinal fluid examination had a value on a par with the Wassermann reaction if not above it. Multiple involvements should be searched for, not only in patients who had neurosyphilis, but in others who might have the beginning of an aneurysm which would cloud their future much as neurosyphilis would do in another case.

Dr. WADE H. BROWN emphasized the importance of epidemiological studies as regarded neurosyphilis. As regarded the duality of strain he thought the clinical evidence was just as strong on one side of the question as on the other, whatever the laboratory might show. He thought they should be very cautious in basing conclusions on theories regarding strain, as we knew too little about it. What they knew was based on animal experiment, and comparisons had been made under conditions not comparable. There was a demand at the present time for more careful epidemiological studies of syphilis and more careful laboratory investigation. They were in need of many more facts and careful examination of strains before they were justified in expressing an opinion. When they had this knowledge it would enable them to get a thorough grasp of what caused this type of syphilis.

Fasting as a Method for Treating Epilepsy.—Dr. H. RAWLEY GYELIN of New York made this presentation in which he said that two years ago he had had the opportunity to observe the child of a friend who was at the time 10 years of age and who had had epilepsy in its most severe form for a period of four years prior to that time. For four years he had had *grand mal* and *petit mal* attacks which had become practically continuous. The child had been sent to numerous neurologists and clinicians in the United States and every-

thing had been tried and nothing had succeeded. At Battle Creek he came under the care of an osteopath who promptly fasted him, the first fast being one of fifteen days. This was followed by a period of feeding of three weeks duration and then by a second fast of four or five days. There were four fasting periods over a period of several months. After the second day of fasting the epileptic attacks ceased. Except during an attack of measles, in 1920, he had had no attack save an occasional winking of the eyes. Following this Dr. Geyelin said he had had the opportunity of seeing two other cases treated in the same way by Dr. Conklin, one of which remained entirely cured for two years and one for three years. These results were so striking that they had undertaken to look into the question of fasting from two standpoints: First, to see if they could confirm the results obtained in a large group of cases, and, second, to see if there was a particular type of epilepsy which yielded to this method of treatment. The most important thing from the standpoint of etiology was to find out whether there was any abnormality of metabolism before, during, or after the fasting as contrasted with that of a normal individual under the same conditions. One case was observed before this line of study was determined upon. This patient was a boy nine years of age, the youngest of eight children. He had been normal until four months before admission to the hospital when he suddenly developed *grand mal* seizures which were typical. These had gradually increased in frequency until he was having from fifteen to twenty-five attacks in twenty-four hours. Food was withdrawn suddenly and fluids by mouth were forced. The only thing given at first was distilled water, then later thin broth. The epileptic attacks stopped on the second day of the fast and had not recurred since. The fast was stopped at the end of the third day because of severe acidosis. This led to investigation of the problem from that standpoint. The cases were selected at random and the report comprised observations made of 26 cases studied from six to twenty months. The ages of the patients ranged from 3½ to 35 years. The shortest duration of the epilepsy in any case was four months; the longest thirty-four years; the average duration was eight years and only three cases had had their epilepsy less than a year before coming under observation. There were 16 males and 10 females. The type of epilepsy had varied from *grand mal* attacks alone and unassociated with *petit mal* attacks to *grand mal* attacks associated with *petit mal* attacks, and to those who had *petit mal* attacks only. The periodicity of the attacks ranged from thirty-five attacks a day down to one seizure a month for five years and then a seizure every two weeks. The average periodicity for all cases was one or two *grand mal* attacks per week. They had started, before they knew what the effect of the fasting would be, on very short fasts, the first fast being three days, the second five days, the third ten days. They found that it was possible for these patients to get through the fasts without discomfort and without ill effects. The length of fast finally adopted was twenty days, though this was entirely arbitrary. There were no reasons why one should not employ longer or shorter fasts. Four only out of the twenty-six cases had epileptic symptoms after the tenth day of the fast. Charts showed the acid excretion during the fasts, before the fast was begun, and afterward. The acid excretion was fairly constant, rising during the fast and coming down on the twenty-first day to where it was before the fast was begun. In closing Dr. Geyelin emphasized that this was only a preliminary report and that he fully recognized that epilepsy sometimes intermitted for long periods of time, as long as eight, ten, or even fifteen years. They could not therefore at the present time interpret therapeutic results. However, two of the 26 cases had remained without sign or symptom of epilepsy for one year or over a year. Six cases treated by one or two fasts had not shown any improvement, and 18 cases had shown marked improvement.

Dr. STANLEY COBB of Boston said epilepsy had been worked over from many angles and by many men, by some of the ablest men in the profession and some of the worst charlatans outside of the profession, so one had to be extremely wary and extremely wise in the

interpretation of the effects of any form of treatment. He felt that it was worth while to repeat that with emphasis. In the past the treatment of epilepsy had been extremely varied, all the way from circumcision to painting the motor cortex with iodine, and from regulation of hygienic habits to psychoanalysis. Luminol, bromides, thyroid, and innumerable other drugs had been tried. From this report one might be inclined to decide offhand in favor of gastrointestinal etiology of epilepsy. We might as well say that the variety of operations devised for the relief of epilepsy pointed toward a certain localization. He thought, however, that Dr. Geyelin's work had given them one important new lead. If one went back over the various modes of treatment it would be found that there was one common factor involved and that was the metabolism of the individual, and Dr. Geyelin's work pointed to the idea that there were changes along these lines. In their laboratory work they had produced convulsions in animals and it was found that various drugs and starvation would increase the ability of the animals to stand convulsions. It was also found that thyroid intoxication increased the ability to withstand the convulsions. He did not claim that the convulsions produced experimentally were a parallel to epilepsy but simply advanced the idea that by various means they had succeeded in controlling experimental convulsions.

Dr. TOM A. WILLIAMS of Washington, D. C., stated that some twelve years ago certain facts led him to believe that epileptic manifestations were due to metabolic disorder. Convulsions occurred in eclamptic states and this they believed to be a state of toxemia; they also occurred in uremia and that was a state. They had found that when the metabolism was improved in these conditions the convulsions were relieved. He then formulated the theory that in epilepsy they were dealing with metabolic states due to a deficiency in the alkalies. On that basis he had treated a number of cases. Some treated on that basis still remained free from epilepsy at the end of ten years. Unfortunately he had not had the laboratory facilities to pursue his theories, namely that toxemia might be the underlying cause of epilepsy and the specific thing involved might be the aminoacids. On that theory he had carried out treatment with some success but not as great as that by management by fasting. This paper was valuable in turning the attention of investigators of epilepsy to the metabolic factor. The neurologists had been dominated by the idea that epilepsy was due to structural changes such as neoplasms, infiltration, etc., but patients with these structural changes only convulsed intermittently. Brain tumor caused only intermittent convulsions and sometimes none whatever. He thought that from that fact they could argue that there must have been a metabolic factor involved.

Dr. Frederick De Lue of Boston said that Dr. Geyelin had given them a very valuable contribution. He cited a case of epilepsy in a boy seven years of age who at the age of nine months was put on adult diet. In two months he showed the results in epilepsy. Notwithstanding the fact that he was a brilliant child he was subjected to two operations for prethipening. When he came under his care he started him on skimmed milk and bread without butter. On this diet he put on flesh and became well of his epilepsy. This child later was so situated that no restrictions were placed on his diet and mild convulsions returned. One interesting factor not mentioned in the paper was the effect of an eye defect on epilepsy. He cited an instance in which convulsions in a myopic poorly nourished child seemed to be influenced by the eye condition. Starvation for a certain period of time might cause great discomfort. He had found that the alkalies and especially lithia and the salicylates had a marked effect upon epilepsy.

Dr. GEYELIN, in closing, gave the loss of weight that occurred with various periods of fasting in children and adults and said they had noticed four things out of the ordinary during these observations. Two of the cases developed marked sinus arrhythmia on the fourteenth day of their fast, without any other symptoms. One of these children was fifteen and the other eighteen years of age. One girl of thirteen years developed a bradycardia, the rate being only 50 per minute. One patient developed maniacal symptoms which lasted for

thirty-six hours. These disappeared, however, without it being necessary to interrupt the fast. In a general way it might be said that the cases with a high acid excretion were those which showed the greatest improvement though this was not always the case. Dr. Geyelin said he wanted to emphasize what all the men who had discussed the paper had brought out, and that was the importance of realizing that the fasting treatment of epilepsy was by no means a cure-all. He doubted whether it would prove more successful than other methods of treatment which had been tried and failed, but at least there was one thing that stood out, that was that when one wanted to relieve a severe convulsion in epilepsy or when one wanted to turn a clouded mentality to a clear one it could almost always be done by fasting. All these patients regained their body weight within three weeks and suffered no ill effects following the fast.

Sulphur Dioxide in the Treatment of Experimental Tuberculosis.—Dr. PHILIP H. PIERSON of San Francisco made this presentation in which he stated that sulphur dioxide was present in many factories, such as storage battery factories, smelters and other industries. It had been shown that sulphur dioxide possessed a bactericidal action *in vitro* but whether it had such an action *in vivo* had not been definitely shown. This they had endeavored to ascertain by giving measured quantities of sulphur dioxide to animals in which experimental tuberculosis had been produced. Two forms of apparatus had been worked out, one for giving the gas in concentrated form and one for giving it in dilute form. In the concentrated form the dilution was 1500-3000 parts of sulphur dioxide to 1,000,000 parts of air, each treatment averaging thirty minutes. In the dilute method the dilution was 1666 parts of sulphur dioxide to 1,000,000 parts of air, each treatment averaging seven hours a day. There were many problems encountered in the use of sulphur dioxide in rabbits, such as diet, apparatus from measuring the gas, capacity and content of the plasma carbon dioxide, and means of estimating the result of each treatment. Roughly speaking the extent of the tuberculosis in the treated animals was about two-thirds of that in the control animals and the progress of the disease in the treated animals was about six-tenths that in the control animals. About 50 per cent. of the animals died of pneumonia and empyema and part of those deaths might have been due to the gas and part to a peculiar susceptibility of the animals for secondary infections. There was need of endeavor to find out what happened to the gas when it entered the animals and of determining its effect on the hydrogen ion concentration and on the carbon dioxide of the plasma. They had found that there was a definite drop in the carbon dioxide of the plasma after treatment, but they did not know the fate of the carbon dioxide in the blood under the concentrated and dilute treatments. Sulphur dioxide exerted an inhibiting effect on tuberculosis in experimental rabbits. It produced a greater effect on the progress than on the extent and distribution of the infection. They expected to be able to show what happened to the gas in the blood and how it exerted its inhibiting action on the tuberculous process in a subsequent communication.

Dr. HALLDORSON of Winnipeg expressed himself as highly gratified that some man had had the courage to take a step forward and to depart from the time-honored method of leaving cases of tuberculosis to nature. It did not matter so much what the results were in this particular investigation; the important thing was that a new departure had been made and that others would now follow. So far as the treatment of tuberculosis was concerned they had been following the same rut for the past twenty years. Sulphur dioxide was one of the substances that had a distinct effect on the tubercle bacillus and the course of the disease. Other substances that were dissimilar and were also acids exerted action upon tuberculosis. They had found from time to time that there was a smaller number of tuberculous patients among those engaged in certain occupations. For instance, it had long been noticed that there were few cases of tuberculosis among sailors and among the workers in salt mines and the same had been said of some coal mines, and the strongest example we had of a substance that would fortify against the action of the

tubercle bacillus was found in lactic acid. All were laminar with the action of lactic acid on the people of Bulgaria. Another interesting thing was that in Iceland where people had lived for centuries on sour milk products, making a kind of junket during the summer which was kept for winter and became very sour, pulmonary tuberculosis was rare. There were different forms of bone tuberculosis but practically no pulmonary tuberculosis except among those who had gone outside of the country. As soon as these people changed their habits and no longer used these sour milk products to such a great extent tuberculosis became a scourge. While he made no claim that lactic acid was a cure-all for tuberculosis, he felt that it would limit the disease to a great extent. He had shown in a paper several years ago chlorine in solution also had an inhibiting effect upon tuberculosis. Leaving the cure of tuberculosis to nature was all right if one did not know what to do for it, but it was a confession of ignorance and helplessness.

Dr. F. L. HEHLER of Washington stated that the attempt to show the effect of sulphur dioxide upon tuberculosis was not new. Back in 1903 Sommerfeldt and others in Germany had experimented with sulphur dioxide in tuberculosis. About 100 cases were reported as having been treated with this agent with excellent results. They did not use a simple mixture of sulphur dioxide but a substance which consisted of oil of eucalyptus, sulphur dioxide and carbon dioxide, though the latter substance played but a small part in the mixture. The sulphur dioxide and eucalyptus were present, however, in sufficient quantities to exert some action. The treatment consisted in placing the mixture on a plate and heating it. As a result of this work propaganda was started and a preparation containing these ingredients manufactured in this country, but the amount of sulphur dioxide emitted when the substance was heated was very small, the concentration not being sufficient to be effective. It was tried out on a number of germs, typhoid, and other bacilli and its result was nil.

(To be continued.)

Chance Cure of Puerperal Fever by Peptonic Shock.—Levy-Solal reports the case of a woman with streptococcal puerperal septicemia which was apparently cured with a single intravenous injection of peptone. Since this treatment cannot be claimed as universally applicable it is evident that an element of chance must figure. There are numerous colloids which might produce this effect, but as yet there is no way of making a choice.—*La Presse Médicale*.

Syndrome of Lethargic Encephalitis Apparently Caused by Syphilis.—Dr. Ricardo Aguilar of Honduras reports the following case in the *Revista Medico-Quirúrgica* for December 1, 1920, ii, 14. A man of 34 was admitted to the hospital at Tegucigalpa last July in a state of lethargy. Fifteen days before he had suffered greatly from headache with fever, this condition passing into stupor. It was learned that he had contracted a chancre 18 months before and three months ago precocious syphilitic manifestations appeared in the nervous centers. There were evidences of meningism and ptosis was present. The patient also showed a risus sardonius and there was nocturnal delirium. Examination showed incomplete transitory pareses of the III, IV, VI, and VII cranial nerves. Other symptoms mentioned were strabismus and vertigo of the pseudo-Ménière type. The Kernig was negative. The lower extremities showed both rigidity and flaccidity. Respiration and pulse unusually slow while the maximum temperature was 38.5° C. There was incontinence of urine and feces, and on the sixth day a bed sore appeared over the sacrum. Spinal puncture showed the fluid to be under high tension but without pathological content. Before making a diagnosis of encephalitis lethargica it was thought necessary to exclude syphilis. Death soon supervened and an autopsy was obtained. The meninges were the seat of diffuse congestion. Softened gummata were found in the region of Broca's convolution involving much of the parietal and temporal lobes. Despite the evidences of syphilis the patient presented the triad of lethargic encephalitis—pareses of the oculomotor apparatus, lethargy, and continued fever.

Miscellany.

MY UNCLE BENJAMIN.*

By EMIL MAYER, M.D.,

NEW YORK.

UNCLE BENJAMIN RATHERY was a doctor, a century and a half ago. He was 5 ft. 10 in. in height, carried a big sword at his side, and wore a coat of scarlet ratteen, breeches of the same color and material, pearl gray silk stockings, and shoes with silver buckles. Over his coat hung a large black queue, almost as long as his sword. It kept bobbing about, and covered him with powder so that his coat, with its shades of red and white, looked like an unbaked brick. He was thus attired because he was a doctor. I do not know whether the patients had much confidence in him, but he had very little confidence in medicine.

He loved wine, not for itself, but for the short-lived madness, which makes a man of wit talk nonsense in so naive, piquant, and original a way that one would like to talk that way always. Uncle Benjamin had principles; he said that intoxication would have been one of the greatest blessings of the Creator, if it did not cause headache, and that the only thing that made man superior to the brute was the faculty of getting drunk.

Uncle Benjamin lived at the time when customs of the little town were not yet glossed over with elegance; they were full of the charming ease and freedom of a lovely simplicity. The characteristic of that happy age was unconcern; bourgeois were not office seekers; the merchants, few in number, then grew rich slowly without doing very much; the laborers worked, not to amass savings, but to make both ends meet.

Benjamin was twenty-eight years old, had practised medicine for three years, but this brought him no income. He owed his tailor for three scarlet coats, and his barber for three years of hair-dressing, and in each of the most famous taverns of the town he had a pretty little account running with nothing on the credit side but a few drugs; and every evening regularly after supper his sister urged him to get married. All this he listened to very attentively, but did not make the slightest use of it.

With delightful humor the author carries us through the adventures of this philosopher and wit, brings vividly before us the customs of two centuries ago, and entertains us mightily with both his humor and pathos.

Uncle Benjamin finally concludes to listen to the thought of getting married, and visits at the home of a Monsieur Minxit, the father of an only daughter, who was very anxious to have an alliance with a physician for the help that it would be to him in his own vocation, as he made a specialty of urines. After twenty years' study of the science, Monsieur Minxit succeeded in distinguishing those that were

clouded from those that were clear, which did not prevent him from telling everyone who came to him that he could tell a great man, a king, and a minister by his urine. He was no more of a murderer than his rivals, only he made more money with his many colored vials than they did with their prescriptions. He had acquired a handsome fortune, and also had the faculty of spending his money to a good purpose. He seemed to give everything as if it cost nothing, and his clients, who streamed to him, always found open table at his house.

Monsieur Minxit gives Uncle Benjamin an illustration of his methods of divination by inspection of the urine, following which a little girl came in. "Well, how is your mother?" asked the doctor.

"Much better, Monsieur Minxit. But she cannot get her strength back, and I came to ask you what she should do."

"You ask me what she should do, and I wager you haven't a sou with which to buy medicine."

"Oh, no, dear Monsieur Minxit. My father has been out of work a whole week."

"Then why the devil does your mother take it into her head to be sick?"

"Don't worry, Monsieur Minxit. As soon as father gets work you will be paid for your visits. He told me to tell you so."

"Nonsense again. Is your father crazy to expect to pay me for my visits when he has no bread in his house? For what does your imbecile of a father take me? Take your donkey this evening and get a sack of wheat at my mill. And take a basket of old wine and a quarter of mutton along with you from here. That is what your mother needs. If her strength doesn't come back in two or three days, let me know. Now go, my child."

Tillier, the writer of this gem of humor, died of tuberculosis at the age of forty-three, in 1844, in poverty. Paris has discovered him within the last few years, after his works have been translated in various languages. His writings reflected his character, his biographer says he was one of those beautiful natures of native nobility, who rise out of the depth of society and, in spite of temptation and misery, pass unsullied through the filth of life. Wholly of the third estate and of the people, he loved liberty passionately and battled for her heroically on the remote outpost that accident had entrusted to him. Regardless of personal matters, he lived for his idea and found his reward in himself. Unselfishness was his virtue, and human dignity his religion.

Although Tillier's pen was often dipped in gall and he railed against the church and its dignitaries, he was at heart devout enough apparently, for when he was dying of consumption he said: "When my last coughing fit has come, when my quill, together with my soul, has returned to God, will the sun darken and the earth cease growing green? The All Father who supplies the young of the birds with food, will He deny it to the little ones of the pamphleteer? My parents gave me nothing, and I am grateful to them for it. Had they given me much I should not dare to sign their name to my pamphlets. When I left the paternal roof I had not even a calling. I fell into this world like a leaf that the storm shakes from the tree and

*My Uncle Benjamin, by Claude Tillier; translated by Adele Szold Saltzer. New York: Boni and Liveright. This translation is the second that has been made of this book in the English language. The first, by Benjamin R. Tucker (1890), contains an appendix, which is omitted in the present translation, in which the story of the struggle for existence that was Tillier's lot is graphically portrayed.

rolls along the highway. But I did not lose courage; I always hoped that out of the wing of some bird sweeping the skies a quill would fall down, fitted to my fingers, and I have not been disappointed."

The warmth of his feeling and the tenderness of his heart burst forth powerfully in these last lines which he wrote on his death bed: "My mother stands beside my invalid's chair; she is deaf, poor woman, and my voice is weak; we can hardly make ourselves understood. But she is here, she envelops me in her glances, she seeks to read in my eyes what I want, she can divine by the smallest fold on my forehead what I dislike. She has left the other half of her family, the half that can spare her; she wishes to have her part of my death struggle. The same care that once watched over my childhood she now bestows on my early old age. One son she has already seen dying, and now she comes to lend me also the support of her arm and to lead me gently down the slope of life. . . .

"Poor mother, with what heavy hand did God measure out the tears that he stored beneath your lids? Or is God unjust to the mothers? A son can only once bury his mother; but a mother, how many sons may she mourn? Am I at least the last child she must bury? Will a last one remain to close her eyes and lay her dear body beside our bones? Or must it be her lot to take the key of our poor house with her? . . .

"Ah! how much less am I to be commiserated than she?" . . .

This story of My Uncle Benjamin abounds in humor, and the style is that of a century ago, when plain speaking was the vogue. In the broad humor one finds, however, no reference to sex, the ungratified passion of the maiden lady of uncertain age, or the yielding to it, with the brute who conquers the aforesaid maiden, in our novels of the present day.

40 EAST 41ST STREET.

Reminiscences of Charcot.—Leon Daudet has just published in the *Revue Universelle* (February 1) an article entitled "Charcot or Cesarism of the Faculty." Comments on the old master are highly favorable, although Daudet hit off some of his neurological colleagues in an uncompromising fashion. He also admired Brissaud, Marie, and Babinski, under whom he had been interne. Babinski had a genius for keeping out of faculty quarrels and intrigues. Charcot, far from being jealous of him, did all he could to bring out his superiority.

Daudet considers Charcot as writer, professor, clinician, and thinker. Of special interest is the account of how the great diagnostician first recognized the presence of the malady which was to destroy him. It happened at a gay midnight festivity at which Pasteur was also present. Charcot was seen to rise from the table ill at ease and to turn pale. He was experiencing his first crisis of angina pectoris, a malady which he had so often described to others. Daudet ran out to get Potain, who lived near by, while another guest went on a similar mission to Damaschino. Daudet sounded the bell insistently and Potain himself answered in his shirt with a candle in his hand. He dressed and hurried to Charcot's house

and after a prolonged interview left with encouraging words. Once out of his presence he gave him two years and a half to live. Two years and eight months later Daudet had a telepathic vision of Charcot seized by a crisis of his malady. He said a prayer for him and at once wrote his father of the experience, feeling certain that Charcot was dead. Nothing happened that day, but on the following a telegram from *Le Temps* to the author, who was at Uriage, asked him for an obituary notice of Charcot, whose sudden death had just occurred. Potain also was sojourning at Uriage and the author grimly recalled to him his prognosis.

The death of Charcot was described by Debove in a eulogy delivered some years later. Debove, Strauss, and Charcot were guests at an inn and had dined together, conversing on many subjects. Charcot went to his room and wrote a long letter to his wife, which was never mailed. At about 3 A. M. Strauss, whose room was near Charcot's, roused him with the information that Charcot was ill. He was in the midst of an attack and had just stated that he was feeling better, when he succumbed. The place of death was a tourists' hotel at Settons, in a solitary corner of Morvan. The author visited the hotel and obtained a firsthand account of the event from the innkeeper. The death chamber had been renovated but the furniture was the same, including the Empire chair, in which the great man had breathed his last. The hotel has no commemorative tablet and the author believes it time to erect one on the façade of the building.—*Le Progrès Médical*.

The Older Votaries of Anatomy and Their Nomenclature.—Many of the names given in days gone by to distinguish the various parts of the human frame have been changed in the latest editions of the classical works on anatomy. In many instances these alterations have been made in the cause of accuracy and correctness, but in some instances the reasons for this revision of nomenclature do not appear to be altogether sound.

In several successive issues of the *Medical Press and Circular*, beginning with March 23, Dr. Charles A. Beck discusses the subject in a series of scholarly and interesting articles. While fully appreciating the improvements in the modern practice in anatomy, as regards both text and illustrations, he aims some criticisms at the new terminology. After pointing out that the carpal and tarsal bones have alien names and that many muscles and ligaments share a similar fate, and allowing that such a change in nomenclature may have much in its favor, he deprecates the omission of the names of the old anatomists hitherto appended to the parts discovered and first adequately described by them. He is of the opinion that their discoveries are worthy of a patronymic accompaniment, and he further holds that the half-hearted way in which these names are put in brackets before giving them the *coup-de-grâce* into the Lethe of oblivion, intended presumably as an apology, is really rather in the nature of an insult. "Few will be the number of students who, in future, may bother their heads about the old pioneers of anatomy whose names were for centuries linked to their

respective discoveries. Thus we find ligamentum inguinale for Poupart's ligament, the Eustachian tube is now tuba auditiva, the Fallopiian tube, the tuba uterina, and so on." The writer is inclined to regard this omission of names of discoverers as a *jalousie de métier*, since dissectional anatomy has nothing new for the knife of the present-day dissector.

Some of the old-time anatomical terms were of Biblical origin, as, for example, pomum Adami, morsus diaboli, lyra Davidis, musculus religiosus, i.e. trapezius, which bears a fanciful resemblance to a monk's cowl. The older anatomists searched long and earnestly for the soul, but failed to find it, or even with any certainty, its seat. Cartenius once thought he had discovered the seat of the soul of man in the pineal gland, but later realized that it could not be confined there.

Another enthusiastic dissector earnestly endeavored to find the soul of woman (although the Koran teaches that they have none), not in the brain, but in the pelvis, but finally gave up the quest in disgust and signalled his failure by a Greek compound longer even than the word, beloved of sophomores, for hash. Beck's review of anatomical nomenclature is instructive and entertaining, and the plea made for the preservation of the names in anatomy hallowed by tradition—that is, when they do not offend against accuracy—is well intended and will doubtless commend itself to many medical men. Some of the changes in nomenclature are obviously for the better, but many of them, "made in Germany," are simply iconoclastic and based on inadequate reasons.

Women of the Public Health Service.—In proportion to its size, the personnel of the United States Public Health Service probably includes more highly trained and specialized women than any other branch of the Federal Government. Highest on the list stand two officers holding commissioned rank in the reserve—Surgeons Lydia Allen DeVilbiss and Josephine Baker. Next in rank come a number of scientific and professional women, all or most of whom are physicians, though some are classified by other titles. Among these are Acting Assistant Surgeons Blanche Sterling and Edith B. Lowry, Viola Russel, pediatrician, and Elizabeth B. Reid, all of the child hygiene section; Ida A. Bengtson, sanitary biologist; Alice C. Evans and Mrs. E. M. A. Enlows, bacteriologists, and Mrs. S. C. Brooks, assistant biologist, all of the Hygienic Laboratory; Gertrude Seymour, president of the American Women in Public Health, and Drs. Daisy Robinson and Edith Rabe, regional consultants, all of the venereal diseases divisions.

Several large groups of highly trained women have been organized in the Public Health Service. Among these are the reconstruction aides, most of whom have had college training or its equivalent and all of whom are of unusual ability and character. These are stationed at various hospitals of the Service throughout the country. Their task is to help maimed soldiers to regain control of injured muscles and nerves or of dormant or deranged mental faculties by appropriate

physical exercises (physiotherapy) or by curative and diversional occupations (occupational therapy). The aides, who are headed by Miss Marian Morris, number about 400, to whom others will be added as qualified applicants can be found.

Vieving with the reconstruction aides are the dietitians, whose section was organized about a year ago to take over from the pharmacists the victualing and food administration of the scores of military hospitals now handled by the Public Health Service. All members of the section, which is headed by Mrs. H. B. Corsette, are graduates of schools of household economics and are thoroughly trained and experienced in all matters relating to dieting. When fully recruited, the personnel will be about two hundred.

The nurses' corps, headed by Miss Lucy Minnerode, consists of nurses who have been highly trained in every-day hospital work and a large proportion of whom are specialists in particular lines, such as mental and nervous diseases and tuberculosis. The corps today numbers 1400 and needs 300 more. All applicants must, however, be graduates of recognized training schools and must be registered either in the State in which they live or in that in which they were graduated. Another body of nurses, 165 in number, who work in clinics and miscellaneous health activities under the supervision of Miss Ann Doyle, specializes in venereal disease treatment.

Death of Von Bunge.—This Swiss scientist, best known to the public through his lectures on physiological chemistry, is dead at the age of 77, and Abderhalden contributes an obituary to the columns of the *Schweizerische medizinische Wochenschrift*. He was an eccentric who was out of touch with modern clinical medicine, largely because of the materialistic viewpoint of medical practice. His writings have furnished ammunition for the foes of scientific medicine, despite the fact that he was a laboratory man pure and simple, and practised animal experiments. The necrologist does not allude to this mental attitude, but eulogizes the great teaching ability of the deceased, not alone in biological chemistry, in which his rank was of the highest, but in physiology as well, for he was equally eminent in this field. An exact scientist, he presented a marked idealism and strong bias toward metaphysics and the subjective viewpoint.

Many years ago von Bunge was a pronounced antialcohol propagandist, and here, as elsewhere, often went to ludicrous extremes. If we remember rightly, he denied that alcohol could exhilarate, and the phenomenon of hilarity in mass drinking he attributed to a sort of crowd suggestion. The latter is a component, of course, but von Bunge admitted no other. This attitude was seen in many other problems, which, although in the opinion of the vast majority of scientists still *sub judice*, were regarded by the deceased as definitely settled, doubtless because of his idealism and moral bias. His complete views, admitting no controversy, naturally made his books very readable and ministered to a frailty of human nature which prefers the air of finality to dubiousness. According to the eminent necrologist, the deceased was not a man for details or for resolutely following up a research no matter where it led.

THE MORAL CENTER IN THE BRAIN

(CORTICAL REGION FOR CONTROL OF MORALS)
ITS LOCATION AND SIGNIFICANCE

BY WILLIAM BROWNING, M.D.,

BROOKLYN, N. Y.

It has long been thought by occasional observers that our higher moral activities are the function of a limited region or center in the brain. Apparently, however, little has been done to decide the matter or to determine the location of such presumed center.

The suggestion that there is such a thing as a moral center in the cerebral cortex brings up an echo of many disputes in which a majority of psychiatric and psychologic lights have shown conclusively (at least in their own estimation) that not only is it non-existent but that it is quite out of the realm of conceivable possibility. "The vulgar idea of moral insanity," as one of them expresses it. Others have had the saving grace to admit that strange cases are sometimes reported. There are still others, a few, who have either had the fortune to meet striking cases or the vision to see that something of the kind was probable.

Benjamin Rush, who recognized this condition very clearly ("Diseases of the Mind," 1812, Phila., p. 359-360), reported three cases of his own observation, and attributed them to organic defect, thus in principle approaching the idea of a center: "In all these cases of innate, preternatural moral depravity, there is probably an original defective organization in those parts of the body, which are occupied by the moral faculties of the mind."

The term, moral insanity, dates from James Cowles Pritchard, M.D. (1785-1848), in his work, "A Treatise on Insanity," London, 1835. His original definition is not now held applicable, as it included mental cases of other type.

Since then many terms and modifications have been introduced. We hear of moral perversity, defect, imbecility, degeneracy, delinquency, depravity, amentia, moral moron, constitutional immorality, anti-social defect, "a moral maniac with a rational intellect," psychological ataxia, "true Daltonism of ethical sentiment," et cetera.

The great majority of such cases are congenital or are lacking in localizing signs, or so complicated as to be worthless for the present purpose. It is not rare in the public press to read accounts of cases so graphically described as to leave little doubt that they are of this class.

Over forty years ago Bannister of Chicago (J. N.

& M. Dis., 1877, p. 661) put it as follows: "Like all the other senses or feelings, this moral sense must have its special mechanism in the brain for the reception of moral impressions. (For various reasons it appears that this apparatus is localized in some particular part of the brain.)"

Reimer (*Deut. med. Wochschrift.*, 1878) thought this defect must come from an organic brain trouble, and compared it to the loss of music and color senses.

Mercier (*Jrnl. Mt. Sci.*, 1894, p. 596) said: "Moral insanity . . . a defect of conduct and motive without any conspicuous intellectual defect." "I am convinced . . . there can be no doubt such cases do arise."

More recently R. H. Steen ("Moral Insanity," *J. Ment. Science*, 1913, July, p. 478) concludes that in these cases the "moral sense center" is congenitally absent, referring of course to the hereditary form. "They are not idiots, or imbeciles and should no more be called such than persons suffering from music-deafness or color-blindness." And on p. 484: "We may therefore postulate a center for music and a center for color. And in a similar manner I would postulate a moral sense center, . . . congenitally absent" in these hereditary defectives.

From this short review it is clear that for more than a century, with increasing definiteness and in such countries as United States, England and Germany, there has been a distinct recognition by occasional good authorities, of the existence of such a center. It is with the hope of definitely establishing this fact that the following histories are presented.

All these observers and thinkers can be given full credit. To the writer, however, the conclusion arose from observing in practice occasional cases of gross defect on the moral side that evidently were dependent on a certain type of cerebral injury. It has taken years of watching these and allied cases, with a trying out of the facts, to form a mental picture, however incomplete, of their psychic status.

It has long been known that cases of this kind do occur, where there is gross moral defect, with preservation of good intellectual or scholarly ability. The principle remains the same whether or not we quibble over relatively intact intellectual powers.

This center may be imperfect through faulty development, through accident at birth or from injury later in life. And like all centers it doubtless is enfeebled by lack of use, and vice versa. It is only cases that show external or other localizing evidence of injury that are for present purposes demonstrative. This greatly limits available material.

The cases to be given differ somewhat in both anatomical and clinical detail. But on both sides there is enough in common to give new and important light. It would be satisfactory to establish both the existence of such a center and the exact

FIG. 1.—Case I. Palpable depression in the right frontal bone, extending up to scalp line.

anatomical limits of all its subdivisions. But the main thing comes first: for this purpose it seems better to put proof on record and not wait longer for details.

CASE I.—J. T., a boy of nearly 14 years, Hebrew race, seen Oct., 1919, through the courtesy of Dr. R. O. Brockway. Father dead. Mother, a plain sensible woman, keeps a small store. A brother of 16 years and a sister of 20 have never shown any abnormality. Treatment is now sought for persistent pilfering, lying, and deceit. There was a history of seizures, first in March, 1917, with loss of consciousness; the next the following May; the third in Aug.; and the last in Nov., 1918. In these the mouth drew to the left, he stiffened out, made a gasping sound at onset, and vomited. All were at night.

Steals money from his mother, but denies it. The money that he steals is found at different places, and he keeps such hidden caches most of the time. Also takes candy and other things from the store. He claims never to have stolen from strangers, but his statements are known to be unreliable. Nothing controls him in these respects; and his conduct has become intolerable as well as most distressing to his mother. "Awful cranky," "Terrible temper," "Fresh," "Very excitable," "He's awful wild," but never runs away.

He is small for his age. Ht. 60 in. Wt. 86 lbs. P. 72. He has a bright, pleasant face, large mouth. Is in graduating class at P. S. Mentally he is clear, quick, and fully up to boys of his age. Yawns. Sleeps 10 hours, shouting nightly, and wakens tired. Fond of music. Head max. circumf. 56 cm. Cephalic index over 76. A cardiac murmur, and precordial pain on running. Pupils react to light. Is right handed. No paralysis anywhere.

His head was injured by the use of instruments at birth. This left a scar and a depression of the bone in the right temporo-frontal region. The depression is most noticeable 4 cm. above the orbital angle on the right. It is palpable to within 2 cm. of the middle line. Nothing of the kind on the left. In some lights a definite white thin scar is visible. The main palpable depression was marked with an actinic pencil, and is thus indicated in the picture.

Dr. Eastmond very kindly made a series of plates in direct transverse and varying intermediary positions. But owing apparently to the obliquity of the furrow he was unable to establish any x-ray evidence.

CASE II.—M. P., 18 years old, born in Brooklyn, of Italian parentage, seen in July, 1914, at Kings County Hospital. The notes of her case were partly supplied by a physician who had examined her elsewhere, partly by Dr. M. D. Jones, superintendent of the hospital, and partly from other sources. She was admitted to the observation ward, but was not found committable as insane and was transferred to the neurological service. Parents living and well. Has three sisters. At the

age of nearly four years she was hit on the forehead with a brick; this required an operation at St. Catharine's Hospital, with removal of three pieces of bone. General health always good. Matured at 14; is regular. Left school at 14, in 6B grade, to work. Never any particular trouble at school with teachers or other pupils. Poor in spelling and arithmetic. Is left handed. Made trouble at home. Insisted on going with a bad girl. Vicious, immoral, wayward. Stayed out on the street late at night. Took a strange man to her room, or lived with him.

In March, 1913, she was sent to a correctional institution. There reported as profane, tried to tear off the Sisters' veils and did tear clothing from other inmates; very abusive, calling them the vilest names, refractory; "vicious, used violent and obscene language, had outbursts of temper, screaming spells, seemed a leader in starting trouble, at times was silent and then quite talkative, would not attend school and when at school would not apply herself; eats and sleeps well." Sullen. No smiles. "She stated that she frequently had headaches, especially in the morning, but otherwise felt well." "She is of an aggressive and forceful personality rather than of the apathetic and colorless. She is a danger to society morally, because of her history, her shallowness of reasoning and her moods. Like many cases she does not show equal defectiveness in all phases of mentality, since she has been able to grasp a certain amount of knowledge, and has been able to retain a portion of it, as shown by educational tests." "A very important factor in this girl's case is her explosiveness, somewhat akin to epilepsy, although of course there are no seizures." So incorrigible, noisy and bad-tempered with outbreaks that it was impossible to retain her with others. "She is in no way insane." "An operation would doubtless show that there is scar tissue underneath which is acting as a source of irritation."

A girl of good physique. Dark complexion. Heart, lungs, reflexes, extremities, musculature, and urine normal. Pupils equal and react to light and accommodation. No weakness of ocular muscles. Circumference of head 52.6 cm. Cephalic index 78.6. Apparently a moderate degree of intelligence. Very reticent when questioned. General obstinacy of manner. Understands what constitutes proper conduct, but cannot explain her actions, except to claim that she cannot control herself. Yet in the hospital she deported herself quietly and properly. A fair memory. No hallucinations.

There is a deep triangular scar on the left forehead near the scalp line, extending obliquely upwards. The scar was attached to a marked furrow in the bone. "A depression a little to the left of the median line of the frontal bone, the upper portion of which goes up into the roots of the hair." The depression extended diagonally about 1½ inches, and was an inch in width. The photo of this scar was made by Mr. Schwöpe at the hospital, July 29, 1914.

CASE III.—A young nian of 20 years when first referred by Dr. J. P. Warbasse in 1908. One grandmother died at 95. The parents and a brother two

FIG. 2.—Case II. Scar covering depression just in the scalp line of forehead on the left.

years older (been no other child) are sterling people. As the writer was acquainted with the family long before, he can qualify as a character witness. He was born with instruments and the maximum traction of a powerful accoucheur. The doctor now only recalls that it was a long, difficult confinement, and that the

infant was temporarily put aside to attend the mother. No scar left from birth. Bottle-fed. First two teeth at ten months. He was not specially backward in learning to talk. But "his whole right side" has always been weaker than his left (hemiplegic). When he first began to notice things, a few months old, he turned his head to the right and swung his eyes back to the left in looking at anything. At the time this was considered "cute." He is extremely left-handed, the only one so in the family. Nocturnal enuresis until about 14 years old. His teeth were very irregular, but have been straightened. When 8 years old he fell against a gate, injuring his right forehead. From this a circoid aneurysm developed. This was cured by a series of operations, and evidently had nothing to do with his condition otherwise. Adenoids removed soon after (1908). And an appendectomy in 1912. Always backward in his studies; one subject about as another; both slow to acquire and quick to forget. He finished grammar school, but did not really graduate because of deficiencies.

Relief was sought for his many delinquencies. When only five years old he stole money at home, and used it to buy things for other children. Later he stole from the seamstress' purse. He "lied up and down" at eight years, and was actively taking things at nine. Came home drunk at 15, though he never became an habitué. Stayed out to all hours of the night, or all night. Five times he pledged a prized watch, and gambled the money. "It seems sometimes as if I would do anything to get money"—and yet he promptly squanders it. He gained a running championship at school, and later pawned the token. Urethritis a year and a half ago. The worst was taking money from a R. E. agent; then he played pool with it. To raise money to clear this he stole a valued ring from his mother. An almost endless number and variety of bad acts were related. "About all these things he has done he has never told the truth," says the father. "I'd have to have the evidence dead against him." He is very penitent after these things happen. "Yet he adds: 'He has the sweetest and most lovable disposition.' 'He doesn't have a realizing sense.' In fact, he has no sense of fear. And as he says, 'Nothing seems to worry me in the least.'"

He had convulsions three times when about two years old; general in character; several weeks apart; without stomach upset; and all starting with a groan in sleep. None since. But he has had dizzy times, formerly so severe he had to grasp some support and seemed dazed. These have gradually lessened to simple dizziness, and are now infrequent. He early became a cigarette and inhaler. Never had summer complaint, and rarely any headache.

Except for scars he is a good looking fellow. Wt 125 lbs. Appetite good. Pulse 72-82. Cardiac sounds clear. Systolic pressure 105. Maximum circumference of head 55 cm. Cephalic index 77. No cranial bruit. External strabismus and slight ptosis on the right, the wall-eye dating from the time when as an infant he first took notice of things. Latent anisocoria (r. pupil the wider in dim light). Each reacts directly and consensually. Some late hippus. Dr. William Simmons reported congenital amblyopia of the right eye, without changes in the fundus (presumably the customary ignoring of picture to avoid diplopia). "I can sleep any place that I place my head," preferably ten hours a night. Not a sleep walker nor dreamer, though occasionally talking in sleep and formerly shouting. Right hand more livid than left. Considerable fine tremor. Left forearm 1.5 cm. larger in circumference than the right. Right elbow somewhat hypo; left not.

A little later he ran away, and was found working on a truck farm in Virginia. In 1913 he made a runaway marriage in another city. Now (1920) has two bright, normal children.

With all this he was never violently vicious, never sought to harm anyone, and was not resentful—partly due perhaps to gentle rearing, or to the fact that intellectually he was more and more able to recognize his shortcomings. He was in the army from Dec., 1917, to March, 1919, and had a good record. The physical training there was well suited to him.

Reexamined in Jan., 1920. General health and appearance excellent. Still has dizziness on the street or

on closing eyes if reclining. Hair turning a little gray. Hearing is good on each side. Weakness but not paralysis of r. eye-muscles. Simple weakness of vision in r. eye, but no limitation of field. "I often bump into things." Lid reflex good. No jaw jerk. "The only thing I eat is meat and potatoes. . . . I never eat fish," nor does he care for cheese, tea or coffee. "Very fond of candy and practically all sweet stuff." "About the best thing I can do is to eat." No interest in flowers. Nasal respiration free. No trouble in swallowing. The fact thus evident that he did not care for things with flavor or odor suggested olfactory loss. And on testing olfaction this was found to be the fact. Smell is poor; at times absent; again (tested with cloves, thymol, toluol in an olfactometer) shows some on the left, but none or always less in the right nostril. It is thus evident that his food peculiarities are dictated by his inability to detect flavors; and there is a high degree of anosmia, especially on the right.

General senses everywhere perfect. Muscle sense intact in right arm. Touch (contact and localization) as perfect over right hand, arm, and face as over left. Because of motor defect he cannot use the right fingers to button or to pick up small objects. But there is no astereognosis. "I used to write a pretty decent hand with my left, then when I went to school I was taught to write with my right." "I just use from my wrist down" in writing. But he is unable to do any free writing with that arm. "When I am writing on the blackboard I have to write with the left hand" as the right arm does not go up well. Grip r. 78; l. 118. He is not conscious any weakness in the right lower extremity, and shows no limp. Achilles jerks present. No clonus. Right knee jerk the stronger. Some crossed jerk each way, or again only to the right. Both right and left abdominal and epigastric jerks absent (at times the case in frontal lesion).

He rarely starts any conversation. But likes to be on the move, and becomes agitated from slight cause. Yawns oft. "I want to do right, but yet I can't do it." "I do a lot of things, and don't seem to care about the consequences until after I do them." "I haven't the brains to run a farm." "I certainly haven't the brains or responsibility a man of 30 should have, I realize that." "I like to go to the movies."

The parents say that since leaving the army his record "has been perfectly straight." But he says he has thrown up three or four positions since without any reason or any place in prospect. He did, however, keep one for six months as polisher of crank-shafts in a western auto-shop, and even sent a little money to his wife. Recently his father sends word that "He is doing all right."

The evidence is clear that he has a lesion in his left or latent frontal lobe. Forceps injuries are frequently here. Then the only sensory loss due to the lesion is anosmia, indicating an anterior lesion. In view of this fact, the former right hemiplegia, and the early conjugate deviation the site of the lesion can with certainty be placed forward of the central convolutions. And as the only lasting motor effect relates to the arm the focus must be in the frontal lobe just forward of that arm center.

In this case a considerable brain lesion still exists. Yet the man's moral status has swung around to a negative state; at least he is no longer actively anti-social. How do these facts harmonize? In the first place the anatomical focus has become relatively less, both from absorption and from bodily development. Then the discipline of years and circumstances may have accomplished something, independent of anatomical change. However, from what we know of cerebral affairs, it is not likely that these agencies fully account for his progress (*v. infra, sub Treatment*).

Case IV. This was a girl from a distance, 13 years old when first seen in 1902. There had been no other child. An instrumental, difficult birth, 16 hours after rupture of the membranes. The attending obstetrician, now gone, was an old friend of the writer's, who well recalls his description of the severe injury at the side of this

infant's forehead, the doctor's anxiety at the time, and his subsequent marvelling at the amount of head-injury that could occur at birth and yet subside and leave no apparent damage beyond a scar. It was the fortuitous knowledge of birth-injury in this case that originally directed the writer's attention to this subject. There was

FIG. 3.—Case V. Scar up from root of nose on the right, with line indicating its extension outwards.

no tuberculosis lues, or familial disorder in the antecedents, unless "rheumatic" touches in some members. Parents and grandparents healthy. Mother plump and ruddy. Father, a good business man, was said to have taken some stimulants, though not showing it.

The child had attacks of bronchitis every winter for the first ten years or so. Said to have been a slight pale frail baby. Grew rapidly between eight and nine years of age, had some twitchings at one time, that brought a fear of chorea but subsided duly. General health more recently excellent. Bright happy child, is fond of study, has done well at school without ever any urging, had a high mark, and in fact is next to the youngest in her class at High School. Memory excellent (by repute and test).

The first erratic conduct noticed was when she invited girls to a party without notice or preparation. But it was trouble at school that brought a definite realization. The details could not be fully learned. But she stole various things, threw teacher's keys out of the window, and when confronted, both lied and tried to blame it on others. These acts were sufficient in kind and persistency to compel withdrawing her from school to avoid the disgrace of dismissal. The parents, it might be remarked, had means enough and were anxious to supply all her needs. She had recently stolen jewelry from a neighbor. Also had injured articles and mused up things she was told to do, and tried to lie it off on her grandmother.

It was for the moral break-down, serious in kind and degree for a girl of her age and circumstances, with the school-suspension, that she was brought for advice. Fortunately the parents, though sadly distraught, were minded to heed and apply advice with unusual care.

She was a plump girl. Wt. 112 lbs. Pulse 92 standing. A little anemic. Tired more easily than formerly. Slept long. Had some frontal ache. Slight stigmata (torus palatinus, attached ear lobules). Is left-handed. The birth-injury now only shows as a small scar above and a little behind the outer canthus of the left eye, this is just at and behind that temporo-frontal angle.

At first she seemed to be suffering from petit mal (occasional sudden faints, once to the extent possibly of falling), but the later course makes this uncertain. Many little nervous manifestations noted from time to time, pain here or there, nausea, dryness of skin, transient dazed feelings, occasional twitches, and hysterical touches. Matured later the same year. And the next she went through an attack of paratyphoid fever.

Under most careful guarding, out-door activities, an anti-chlorotic regimen, private tutoring, and a plan of appeal with objectives to tract, she dropped the bad ways, acquiring a superior physical condition, then entered college. She finished the full course, and was one of the class leaders in both scholarship and popularity. Her subsequent career has been highly creditable in all respects, mentality, judgment, family attachment, kindness, tact, all admirable.

Case V. From data kindly supplied by Dr. Frank L. Christian, Superintendent of the Elmira State Reformatory, where this man had been an inmate. He was 29

years of age at the time of his admission in 1905. Heredity excellent; parents well educated (father a professional man) and prominent in their community.

This man graduated high in his class at one of our best technical schools. He then entered the army, and had a fine record as an officer, his associates speaking well of his mental and moral attributes up to the time of his injury. Moderate user of alcoholics.

While on service in the Philippines he suffered a severe wound (by a bolo) in the frontal region to the right of the median line. This was just supraorbital, extending indefinitely outwards for some distance. Surgically he made a good recovery. The main scar is shown in the cut (taken from a photo in the institution's records). The scar reaches (in the photo) up from the root of the nose, a trifle to the right of the mid-line, about 2 cm. There are also smaller scar-markings continuing outwards over the right lower forehead. The thrust penetrated the right lower frontal convolutions to an unknown depth.

From the time of the injury his character became changed. Some time later he was arrested for forgery. He was then placed in a sanitarium. A year or two after this act he was again arrested for forgery, and sent to the Reformatory. After his parole he drifted from his family connections, and was arrested for impersonating an officer. All trace of him has been lost for some years.

Case VI.—For this I am also indebted to Dr. Christian, who has most courteously gone over their records of recent years for available cases. B. X., age 20 years. Received August, 1917, for the crime of Attempted Grand Larceny, maximum sentence 5 years. Previous criminal history as shown by our records was:

1914, disorderly conduct, \$2 fine. 1915, the same, 2 months in workhouse. 1916, the same, 6 months N. Y. C. Reformatory. 1916, carrying concealed weapons, suspended sentence. Bench warrant for violation of parole. Paroled October, 1918, arrested on charge of robbery, discharged for lack of evidence. Unemployed for several weeks. Later he was shot and killed in a saloon brawl, dying without regaining consciousness.

When five years of age he had received a compound fracture of the skull as the result of being run down by a heavy truck. Soon after this injury epilepsy developed, but the frequency and severity of the seizures gradually lessened as he reached maturity. This man had a large irregular scar extending from the right supraorbital ridge and from the nasal process upward, and obliquely across that os frontis, converging near the border of the scalp and diverging over the coronal suture. He left public school when 14 years of age,

FIG. 4.—Case VI.

having attained only the 6th grade. While at the Reformatory he was quiet and made good progress.

Case VII.—Youth of 14 years, *Irish extraction, examined by Dr. Elliott and the writer, in Sept., 1920, at the reformatory. Mother is in good health. Father, a cooper, died of blood-poisoning nine years ago from an injury of the arm. One older sister is normal. There has been no other child. When 6 years old the boy suffered an accident for which he was treated at a hospital. He claims that no trephining or other operation was done

*For knowledge of this case, as well as important items and an opportunity to examine the youth, the writer is greatly indebted to Hobart H. Todd, late Superintendent of the New York City Parental Home in Queens County, and now head of the New York State Institution at Industry, N. Y.

except sewing up of a head wound; and the hospital "books show that he had a lacerated scalp, but we have no record of his being operated upon." He reached the 4B grade at school when 10 years old. This lad was committed to the reformatory by a City Court, April 20, 1918, for petit larceny. "When he came to us he stated that he had had two previous arrests, and had been discharged." "Since coming here he has escaped twice and has been sent to the Disciplinary Cottage at three different times. He is now (March, 1921) at the Disciplinary Cottage and has been making a good record there for some time past."

At the time seen he was in the Disciplinary Class as a result of his misconduct in the institution. "I was in another cottage and ran away," is his explanation of restrictions. In point of fact he was put there because he had planned, organized, and started a combined attempt at school delivery. The scheme was to overpower the night guard, seize weapons, subdue all opposition, and make a forced exit for those in conspiracy. By the time the first watch had been attacked, some of the plotters got tender feet, and soon the outbreak was quashed. The whole scheme was well thought out, and very nearly a success. It was by far the most serious attempt of the kind ever made at the reformatory, and showed superior ability of its kind.

The patient is blond, well oriented, a little pale. He stands erect. Is definitely right-handed. No tremor. Has never had "fits." No palsy. Looks a trifle undersized, but is about up to the average of his associates. Nose a little prominent; and forehead goes up vertically from root of nose. "A lot of headache," bitemporal. Ears well shaped. Maximum circumference of head 56.0 cm. Cervical glands not large. Thyroid seems normal in size. Teeth fairly good, clean. A slight cast in the right eye. There are two scars on the right forehead. One of these (a heavy cross-scar) resembling a large multiplication mark, is out near the temporal angle and fully half way up to the scalp. The other, quite distinct from the first, is a long scar, somewhat higher up, slanting downward to the left, and extending a little across the midfrontal line about half way up the forehead. On palpating we find in addition a marked circular depression or defect in the bony cranium, a half inch in diameter, at about the coronal suture and just to the right of the middle line. This feels like an old trephine opening, but there is no perceptible scar, and both he and the hospital authorities as noted above deny any knowledge of it. In any event both the history and all the findings are of a right frontal injury or injuries. Personally this youth makes an excellent impression, alert, sober, self-contained, shrewd in his replies, with nothing amiss in manner or appearance beyond the scars. He readily gains the interest of visitors.

Case VIII.—For this the writer is specially obligated to Wm. F. B. Burke, M.D., of the Groszman School at Plainfield, N. J. It refers to an only child, now a young man of 22 years, the prospective heir of a large fortune. The father is a man of the best type, of exceptional integrity and rigidly upright. The mother may be a neurotic, though the only criticism is that in her natural efforts to shield the junior from paternal ire she sometimes indulges in fibs. Some remoter relatives are said to be sexual neurotics.

The son has a large scar on the right in the middle frontotemporal region, extending anteroposteriorly at about the level of the midfrontal convolution. This was the result of a severe instrumental birth. He is right-handed. Graduated from High School, though hardly on his merits. Is already bald. Is large and fleshy, weighing about 200 lbs. "A wonderfully glib talker." "He can sell anything." But when he had a job, "he put all the money in his pocket." "His sense of moral responsibility doesn't exist." "He thought nothing of buying \$20 worth of candy a night for the nurses of a training school his father was interested in." He ran up \$14,000 of bills in one year, besides more that was side-tracked. "The most picturesque liar"; and at the same time he would claim "everybody else was a liar."

His unbridled sexuality made lots of trouble. In one case of mere attempt, some thousands were absorbed in settling it. Maids could not be kept in the house. Once when he was at a social dinner with his

parents, there was a sudden yelling among the servants; he had slipped down right in his evening togs and tackled the first girl in sight. For the protection of self and others he was declared incompetent, and finally castrated; this quieted his sexual excesses, but did not aid further. He has fine manners. "He is a perfect gentleman," excellent company. "The girls flock around that boy." "He has repeatedly impersonated physicians."

Case IX.—This case was contributed by an accomplished colleague familiar with all the details. It refers to a man of 27 years, a first and only child. The father was a very successful business man. Both parents of steady old German stock, musical, but not specially scholarly. The grandparents ditto.

It was a forceps birth; head impacted in pelvis, and instruments applied very obliquely. The left lower side of the face was cut by one blade. The head was badly compressed. The other blade caught the cranium on the other side, "very wide deep scar even now," this begins at the middle of the right frontotemporal angle, and extends back into the parietal region.

He was very slow at studies, not because he was stupid, but because he did not know how to apply himself. "He was impish in play and in teasing." Cruel "as a child." Left school at 14, still in a lower grammar grade. He would take or appropriate any valuables of his father or the family; spend money; run in debt, make his father pay his bills when he was very young, bought extravagant things, useless and foolish. Profligate. Untrustworthy.

"Sexually precocious both in development and desire." All sorts of sexualities, even before puberty. "Got entangled and had to marry at 17, a widow" with a past and three unknown children.

He was not so directly a liar as an "exaggerator" and "embroiderer" of the truth. Recklessly fearless, as a boy of 14 he wagered that he could drive up Broadway at 60 miles an hour and not be arrested—which he accomplished by bribing a fireman, thus winning his bet. At about that age he smashed his father's auto while joy-riding. In fact "all sorts of escapades." Only environment and careful guarding kept him from being a criminal.

"When small he'd go into frenzies if he could not have what he wanted." Is right-handed. Rather slightly built. Usual weight about 135 lbs. Has never shown any motor or sensory involvement. Is not an alcoholic. Never any convulsions. Very gentlemanly, very polished manners. "So long as he can be supervised, he can run a business well."

Case X.—Contributed by Dr. John L. Macomber of Brooklyn, late Superintendent of the Kings Park Asylum. It figured at the time as a legal case, and in that way the particulars were well canvassed and are doubtless still of record. James McB., age 33, white, of Irish extraction, married, father of 4 or 5 children, a truck driver by occupation. Previous to the accident he had enjoyed good health, worked steadily, was sober, honest, and a good provider for his family.

On Feb. 1, 1908, his truck struck a hole in the pavement and he was thrown on his head, striking on the stone pavement. He suffered only momentary unconsciousness, picked himself up, drove to the stable, and put up his horses. He vomited at the stable and again on reaching home. He complained thereafter of headache and disturbance of vision. On examination he was found to have sustained a depressed fracture of the right frontal bone. The fracture evidently involved both plates, and the orbital plate as well, as the eye was dislocated. A careful examination failed to find any injury to the optic nerve or globe, but he suffered from diplopia and headache. Protrusion and displacement of the bulb downward accounted for the diplopia. There was a large incision transversely by five eighths inch in depth and about an inch in vertical measurement. This did not reach the mid-vertical line at any point.

The most marked symptoms, however, were from the change in his moral sphere. After the accident he gave himself up to drink, which he could not tolerate, worked irregularly or not at all, neglected his family, was arrested several times for fighting, thievery, and intoxication and was a pathological liar, as was de-

veloped at the trial, lying even to his lawyers all the time. He became a common bum, deserted his family, and was finally lost track of some five years ago. He was right handed.

(To be continued.)

VACCINATION AGAINST TUBERCULOSIS.*

BY KARL VON RUCK, M.D.,

AND

ROSSELL E. FLACK, M.D.,

ASHVILLE, N. C.

SINCE the discovery by Jenner of preventive vaccination against smallpox, we have been justified in the hope that suitable vaccines would be found which would in a like or similar manner succeed in protecting against other infectious diseases. The reason that no progress was made for almost a century was that the underlying biological principles were not understood, that bacteriology had to make its advent or had not as yet accomplished the isolation of the specific virus responsible for the disease against which we wished to vaccinate.

That the spontaneous recoveries, or the difference in the course of tuberculous disease had some relation to autoimmunization, apart from the virulence of the specific bacillus, was more earnestly considered after historical studies of tuberculosis had shown the difference in its evolution and progress in different races, which were shown to be comparatively slow and often symptomless for long periods of time in races that had been permeated and had suffered from it for centuries; whereas in remote and aboriginal races, which had previously been free from tuberculous infection, the disease ran an acute and rapid course resembling typhoid fever and proved almost always fatal after its first introduction among them. Similar changes were pointed out in other infectious diseases, notably syphilis, without our being able to account for the more benign course, as it is now observed.

In races in which tuberculosis had been present as long as we have records of it an acquired resistance had to be postulated to account for the differences, and in order to increase this apparently acquired resistance artificially, vaccination with the specific virus naturally suggested itself.

Our own studies in tuberculosis have convinced us that the defensive substances can pass from the mother to her offspring *in utero*, and that an active immunization can occur by the passage to the fetus of toxins circulating in the mother's blood.¹ It is, therefore, not an entirely Utopian idea of Reibmayer, who holds that with the prevalence tuberculosis has reached and with the favorable modification of its course in the past, the time should come when it will disappear as a serious disease in the form we know it now, and that the human race will eventually resist infection completely.

In the meanwhile we hope that this remote period can be anticipated by acting now and by accomplishing the object with the administration of a suitable vaccine, as we now have it. All students in immunology will agree with the view

that it is because of the production and increase of defensive substances in the course of infectious diseases that they become self-limited and the patient recovers.

The defensive substance, which stands in relation to a favorable course in tuberculous infection, or checks and retards the disease, and which may in time cause a spontaneous recovery, begins to develop immediately after the first infection, at the point of localization, and unless the bacilli are promptly destroyed, or encapsulated, their increase and extension cause their toxins, as well as the defensive substances, to increase and to appear in the circulation, without which sensitization, as we can demonstrate it by a local skin test, could not occur.

The resistance of the human organism to the tubercle bacillus is, however, not great enough always to destroy the bacilli without previously being immunized, and varies naturally in degree in different individuals. It is further influenced by the virulence of the bacilli that find access to its tissue. Therefore, we must expect periods of extension and recession of the local process, which correspond with the advent of toxemias and of increase of resistance, in the latter case, when the health is not disturbed. Thus, the balance between two contending forces—tubercle bacillus *vs.* resistance—may be lost time and time again without the occurrence of marked symptoms that attract attention.

In our experience this specific resistance or immunity against tuberculosis can be increased even with a small diagnostic dose of any of the fractions which may be obtained from the bodies of the related bacilli. To increase it against the whole bacilli, all fractions thereof must, of course, be present in the dose. In order that a maximal degree may be assured we must give the dose large enough or slowly increase it.

The efforts of immunization against the pathogenic action of the tubercle bacillus date back to the period of its discovery, and become more numerous and persistent with Koch's subsequent discovery of tuberculin in 1890. Animal experimentation with it and therapeutic observations from its use did not yield the expected results, and they were at best unsatisfactory or contradictory. It is now easily understood why it could not have been otherwise, since we have learned to distinguish between the different forms of immunity, especially the antitoxic and antibacterial, or bactericidal forms. We have also learned that to produce an antibacterial immunity we need the body substances of the bacilli (endotoxins), rather than the poisons (exotoxins), which they produce during their growth and multiplication in artificial media. We have further learned that the tubercle bacillus does not endanger life by its secretory or excretory products, which are the specific substances found in tuberculin. These facts were recognized at about the same time by Koch and von Ruck, the former publishing his observations with a modified emulsion of tubercle bacilli in April, 1897, while von Ruck reported on his work with a watery extract made from the bodies of tubercle bacilli a few weeks later. With the latter he obtained his first unquestionable

*Read by Dr. Flack at the Tri-State Medical Association, Spartanburg, S. C., February 17, 1921.

results in the immunization of animals. With either of these products it was possible to produce and to increase the appearance of specific antibodies in the blood of experiment animals, and also in human subjects treated with them.

In 1903, von Ruck applied his watery extract of tubercle bacilli—as the first—for prophylactic purposes in a child one year of age, and thereafter continued his efforts in practical experimental and biochemical investigations, seeking to produce a more efficient vaccine from the bacillary body substances and avoiding the use of bacilli emulsions. The results of these studies and observations in the treatment of tuberculous patients appeared in various reports and publications during the years following, and those obtained from his later vaccine against tuberculosis were made public in 1912.³ Greater details are given in his book published in 1916.⁴

Efforts in prophylactic immunization of children were made later by Petrusky and others in Europe. In this country, Webb and Williams immunized monkeys with living tubercle bacilli and applied their method also in a few children.

We have frequently been asked in what respect our vaccine differs from the various tuberculins and from the tubercle bacillus emulsions which are available in the market, and, while this question has been fully dealt with by one of us in our publications,⁵ we may say here that it contains only the albumoses, albumins, nucleo-albumins, fatty substances, and lipoids of tubercle bacilli, in proper proportion, obtained without subjecting them to physical or chemical injury, and represents all organic body substances of the tubercle bacillus in solution.

On the other hand, tuberculins as first made by Koch, and thereafter by others, are derived from the liquid media upon which tubercle bacilli have been grown and have thereafter been filtered out; they contain, therefore, little or no bacterial body substance, while emulsions simply represent the tubercle bacilli after having been separated by shaking or grinding of the bacillary mass, the emulsion being sterilized by heat.*

The subject of vaccination and of biological diagnosis in the efforts to reduce the morbidity and mortality from tuberculosis and consumption appears of such paramount importance that it cannot be ignored, simply because someone has said he did not believe in it, even if this someone were a most eminent physician. Prejudices have hindered progress in every human endeavor, whereas conservative criticism has always been beneficial. No one is, however, entitled to either, unless he has himself fully investigated the subject under consideration and has examined fully and exhaustively the claims which other reliable investigators have made; and has himself the necessary training and ability to do so.

Knowledge and experience are acquired gradually and new methods and advances for the betterment of conditions, whatever they be, are likewise developed gradually. If these are concerned with the prevention and treatment of dis-

ease, the first condition in their practical application must ever be that of safety; that is, there must be sufficient evidence that no harm will follow, which becomes more and more assured with the number of applications and the time that has elapsed. It is estimated in regard to the *benefits* that are claimed when numbers and time also become factors in the final judgment. In the application of a new method or remedy with which we have no previous personal experience, it is essential that we do not deviate from the one recommended by its author until we believe ourselves competent to improve it.

Coming now to the practical side of our subject, we remind you that in the light of our present knowledge tuberculosis infections occur in childhood, and as a rule not in adult life. In an analysis of reactions of 1,315 individuals¹ no reaction of any kind was noted in 25, or 1.7 per cent.; local reactions only occurred in 366, or 28.3 per cent., and general febrile, or focal reactions, were observed in 924, or 70 per cent. We may, therefore, conclude that no infection had occurred in 1.7 per cent., that there were no tuberculous lesions accessible to the circulation in 28.3 per cent., and that 70 per cent. were actually tuberculous and liable to further progressive disease.

Including previously vaccinated cases with the above, and adding vaccinations made since, we have a total material of over 3,000 children vaccinated since 1903, and apart from the biological tests of the blood and the general and local improvement which followed promptly, we have become aware of not a single case in which there was reason to assume that their tuberculosis recurred or became active. We have been particularly interested and observant for possible relapses or the occurrence of active clinical disease. Many of the children have become adults and have married, and, while we have no statistics to offer, we believe that so far there has been no reason to doubt that our efforts in their behalf have produced the desired result. Many of them have been repeatedly examined by us personally. We are, nevertheless, fully aware that the time intervening since their vaccination is entirely too short to form final conclusions, and to assume that the results are actually permanent. We have, however, the satisfaction of knowing that in those whose general condition was more or less impaired, prompt improvement to normal conditions followed, and that all the tuberculous lesions and stigmata which we observed disappeared and, as far as we can ascertain, they have not returned. In addition, we are ahead in time for the forming of final conclusion, and we, as well as other physicians, are going on in the work without reason to doubt the eventual outcome.*

In the studies referred to it appears that unless we resort to vaccination in the first years of life we must, as a rule, reckon with an infection already accomplished, and that children in a tuberculous environment should, therefore, be sub-

*Much of the work in prophylactic and therapeutic employment of the vaccine has come under the personal observation of Dr. Flack, before and since his association with Dr. von Ruck. He likewise participated in the biological studies and experimental work upon animals in 1913.

³Some of the emulsions, as for instance Koch's, have also been designated "tuberculin." Thus Koch called the one introduced in 1891 "tuberculin R," and a subsequent one "new tuberculin."

jected to it immediately or soon after birth. Further, that in 28.3 per cent. of our cases the infection has been overcome, or the lesions have become obsolete, and in these the acquired immunity must have been sufficient.

It follows that our vaccinations were made in 70 per cent. of already tuberculous children, and that in those we cannot speak of it as a strictly prophylactic measure against the acquirement of tuberculosis, but must consider it rather as a prophylactic one against consumption by removing the lesions in the truly early stage of tuberculosis, which at present is rarely recognized.

Unless children came under medical observation for other reasons, no diagnosis would have been made, except in very few, whose symptoms would have pointed the way and in which the ordinary physical methods would have established it. The latter methods would have failed in most instances or would at best have led to a doubtful attitude on the part of the average medical attendant, even if he had not had an opportunity to examine. For confirmation a tuberculin test would have been necessary, and this is rarely made in general practice.

To establish positively a diagnosis in the truly early stage of tuberculosis we must resort to biological reactions, rather than to the search for physical signs, which may be slight or absent; and unless destructive processes are also present, their advent is still too frequently awaited, when tubercle bacilli in the secretions decide the presence or absence of tuberculous disease.

With the approach of that stage which means pulmonary consumption or ulcerative processes elsewhere, more decided symptoms appear, and it is only then that medical aid is sought. It follows, therefore, that infected children must be sought out, and the examination must include a biological test. The latter is much easier than it is supposed to be by physicians unfamiliar with it, and it has the additional advantage that a positive result occurs regardless of the localization of the lesions, which in young children are less frequently in the lungs and most frequently in glandular structures, especially the bronchial and mesenteric groups; and, unless greatly enlarged, they cause no symptoms which would direct attention to them.

Selection of Cases.—There is really no selection of cases. Every child should be vaccinated, although we would naturally defer the administration of the vaccine in instances when other diseases are present, and especially when the symptoms thereof would interfere with the observations of reactions, as, for instance, fever or acute catarrhal affections of the air passages. Vaccination may be resorted to at any time and the earlier it is done the better is the prospect that no infection with tubercle bacilli has occurred. There is really no reason to delay even an hour after birth.

Before administration of the vaccine a record should be made of the present condition. This should include age, sex, weight, temperature observed for at least 24 hours, respiration and pulse, palpable lymph glands of the cervical, axillary, and inguinal groups, the state of the skin, and

general appearance, as well as abnormal changes found by auscultation and percussion. A short history of previous diseases, and of tuberculosis in the family or of known exposure should be part of the record.

Inasmuch as the vaccine is not obtainable through trade channels and must be ordered directly from our laboratory, and since the directions for the use of the vaccine are as follows: the maximal dose of the undiluted vaccine given below may safely be given at one administration in the first month of life, or later if the absence of tuberculous infection is assured; otherwise, when tuberculosis is liable to be present, by gradually increasing doses.

In the adjustment of the individual maximum doses, intervening age periods and body weight should be taken into consideration.

In the light of our experience the great majority of all children have acquired an infection and the frequency increases with age. Children who belong to tuberculous families or who have been knowingly exposed appear to be all infected, excepting infants under one year of age, in whom the positive findings are less frequent.

Inasmuch as such infections need not manifest themselves by physical signs or symptoms, and the child may as yet appear in perfect health, it is evident that we can never be sure that no tuberculosis has been acquired, and the diagnosis in such instances can only be made by the resulting biological reactions which follow the administration of a suitable tubercle bacillus vaccine. It has, therefore, become our practice rarely to attempt protective vaccination with a single maximum dose, and, although we have seen no harm resulting from very severe reactions which we have met unexpectedly, we find that such reactions are alarming to the parents and friends; and in private practice it is undoubtedly the wisest plan to avoid them as far as this is possible. This may be done by giving, first, a minute trial dose, which, if dilutions of the vaccine are not at hand, may be done most easily by taking up into the syringe 0.1 c.c. of the vaccine and then adding 0.9 c.c. of sterile (boiled) water. This makes a dilution of one part of vaccine to nine parts of water, and if we inject 0.1 c.c. of this the dose given is 1/100 c.c. of the vaccine. The balance left in the syringe may be used upon other children if such are ready to be vaccinated at the same time, otherwise the fluid is thrown away.

We as a rule inject for the first dose 0.4 c.c. of this dilution, and if no reaction follows we resort to 0.1 c.c. of the undiluted preparation. So long as no general or local reaction (at the site of the injection) follows, we double the subsequent dose until we obtain a general (febrile) reaction, which we accept to have occurred when the temperature has risen at least 1° F. or a focal reaction is evidenced by the increase of the physical signs of the tuberculous lesion. As a rule the temperature rise should govern, and the dose which is followed by a distinct rise of temperature must not be increased, but must be repeated after five days from the time when the temperature is again normal, which is usually the case in 24 to 36 hours. Temperature rises that start later than 24 to 36

hours have another origin and cannot be attributed to the dose of vaccine administered. The same is true if no local reaction has occurred at the site of injection, but inasmuch as the local effect may be very slight or transient, it is well that the physician take proper precautions for its recognition by the person in charge, and that the child be examined by himself on the following day.

It will be found that several or more numerous doses will be required by this slower and more conservative administration, and the more extensive or the older the tubercles are which are present, the longer will it take to free the organism of their presence. It naturally follows that if extensive enough to cause recognizable changes the treatment will require longer time.

The maximum dose having been reached and no general or local reaction having been obtained after its administration, the case is to be dismissed unless it be one in which manifest tuberculous lesions have been and are still present, which, however, represent as a rule advanced stages of the disease, and in which further increases of the doses of the vaccine may become necessary.

Since it will be found that with the advent of the age of adolescence most children have acquired a tuberculous infection, the method of vaccination has for its object the removal of tubercle in order to protect the child from the detrimental effects of destructive processes in the tuberculous tissue, which in the lungs constitute consumption.

To exclude a preceding infection, neither a focal nor a general reaction should have occurred to any dose, including the maximum dose for the particular age period. Experiences thus far point to the correctness of the conclusion that a fever reaction following a full or smaller dose of vaccine is indicative of the presence of a latent or of a slowly progressing tuberculous process, while if only a local reaction occurs after a full dose, without rise in temperature, it indicates that tuberculous changes resulting from a previous infection are sufficiently remote from the circulation that they may be considered as encapsulated or obsolete.

Specific Reactions.—Local reactions at the site of injection occur in all cases that have or have heretofore had tuberculous lesions, whether these are healed or not. The reaction consists of redness, heat, and swelling diffused over a larger or smaller area where the dose was injected; the part is painful on pressure or may feel lame and tired. As a rule the local reaction reaches its acme in the course of 24 hours and then disappears rapidly. A slight rise in temperature, not over 0.5° F., may accompany the local reaction if it is of a more severe type, when it also lasts longer.

Local reactions do not occur in children or adults who have never been infected.

Focal reactions—that is, reactions in tuberculous tissue in the lungs and in other tuberculous lesions—manifest themselves by an increase of the previously observed physical signs or symptoms. In so-called open, i.e. advanced cases of pulmonary or laryngeal tuberculosis, there is also

an increase in cough or expectoration, or both, lasting for a day or two, after which they subside, and frequently an amelioration of the symptoms is manifest thereafter, the cough being less frequent and easier; if expectoration were present before, it becomes less and changes in quality to a more mucous type. Upon tuberculous lesions of the skin or visible mucous membranes, as in the mouth, nose, or larynx, focal reactions are readily observed, consisting in circumscribed tumescence, redness, and swelling; joints are apt to show swelling, sometimes tenderness with or without spontaneous pain. Bone lesions react in a similar manner, but not as markedly as do joints. Tuberculous ulcers and fistulae show increased secretion. Lymph glands, especially when of recent involvement, or in a state of progressive enlargement or of caseation, are liable to become swollen and tender. Tuberculous kidneys may show tenderness on deep-pressure, or the focal reaction may be indicated by a dull aching, or by a sensation of weight, while tubercle bacilli are particularly likely to appear more numerous in the urine, if there is an open caseous lesion communicating with the renal pelvis. In tuberculous ulceration of the bladder the symptoms may be increased temporarily, and a similar increase of the symptoms of the tuberculous process may occur in other localizations. Not all tuberculous lesions show focal reactions at the same time; viz., focal reaction may occur in one tuberculous area in the lungs and not in others, or in extrapulmonary lesions and not in the lungs at the same time to a given dose.

General reactions cause a sense of fatigue and lassitude, vague pains in the back, bones, joints, sometimes nausea, etc. They are, as a rule, attended by more or less rise of temperature which may amount to 2° F. and more; exceptionally, rises to 103° and to 104° F. have been noted in instances when the dose had been increased too much.

Reactions, either local, focal, or general, can occur in the course of a few hours after a dose or they may not be observed until 24 hours thereafter; as a rule they have reached their acme by the end of 24 hours, when they subside more or less rapidly. But it may also take two or three days before they disappear entirely. If the general reaction is marked, the patient should be kept in bed.

Although no serious consequences from any form of these reactions, singly or combined, have been observed, yet severe general reactions are undesirable, especially in weakly patients, as likely to interfere with the patient's desire and ability to take food. Patients, however, often claim to feel very much better than before the reaction was experienced, and, as stated before, focal reactions frequently are followed by marked and rapid improvement of the physical signs.

All reactions tend to grow less marked and in time none occur on the continuance of the same dose; they recur after one or several further increases in dose; eventually they disappear entirely, even to the maximal dose.

When all tuberculous tissue accessible to the circulation has disappeared by absorption or has

undergone fibroid transformation or cicatrization, no further focal reactions can be produced.

In normal—that is, in non-tuberculous persons—no reactions occur; in them there are neither redness nor swelling at the point of injection, nor any subjective or objective symptoms.

It has been found that a greater degree of immunity develops at the site of injection, and this may completely neutralize a subsequent dose if it is injected in the same place. It is, therefore, necessary to vary the site of injection. The local neutralization of a given dose may be presumed if no local reaction follows its administration in tuberculous subjects.

Much more might be said of and be added to this very important subject, to the study of which Dr. von Ruck has given his entire time, and which he is still pursuing with his associates.

The facts to emphasize are:

1. That tuberculous infections can be prevented only by vaccination.
2. That the certain diagnosis of the presence of tubercle in the organism can be made only by resorting to biological tests.
3. That tuberculous lesions still accessible to the circulation can be made to disappear by the use of specific vaccines.
4. That the rapidity and uniformity of the results depend upon the time elapsed since the infection has occurred, the extent which the lesions have reached, and the degenerative alterations which are present in them.

TREATMENT OF STERILITY BY MEANS OF ORGANIC EXTRACTS.*

BY ABRAHAM BERCOVITCH, M.D. C.M.,

WINNIPEG, MANITOBA.

GYNECOLOGIST TO THE WINNIPEG GENERAL HOSPITAL; LECTURER ON CLINICAL GYNECOLOGY, UNIVERSITY OF MANITOBA.

As this subject is a very extensive one and the time allotted comparatively speaking very short, I have attempted to prepare an outline of the underlying principles and as near as possible describe the types found in the various cases of sterility which are due to a dysfunction of one or more of the endocrine glands.

In order to gain any benefit from the use of the organic extracts, it is necessary that the case should be one in which the sterility is due to some disorder of the endocrine glands. It is further necessary that there should be definite knowledge as to which of these glands is at fault and also that it should be definitely ascertained whether the gland or glands involved are secreting too much or too little. It is further requisite that the interrelation of these glands and the correlation of their several actions should be appreciated.

During the past few years a mass of literature concerning the ductless glands has accumulated, but the real study of this subject is in its infancy. Very few have either the time or the knowledge

to devote to the matter and the studies at the present are for the most part confined to clinical observation. Not until thorough and complete studies are conducted by groups of workers and persevered with may we hope for concrete gain in organotherapy not only for sterility but for other conditions which are often seen in our institutions hidden under the guise of dysmenorrhea, neurasthenia, retroflexion, menorrhagia, metrorrhagia, etc., which are unclassified, unstudied, and unrelieved. Pathologist, pharmacologist, and biological chemist must be enlisted in the work to cooperate with the clinician.

It must be borne in mind that probably the whole of the ductless gland system is related to the genital functions. Further, sterility may be due to several factors which are entirely beyond the control of these ductless glands. Formerly it was the custom to treat every case of sterility by dilatation or curettage. To treat every case of sterility now by administration of the glands of internal secretion is just as irrational and just as unscientific. If one is convinced that these endocrine glands (one or more) are at fault and if one can say which of them are involved and can further give a reason for his belief that the administration of certain extracts should be of service, then one is justified in prescribing these products.

Although the process of menstruation and the nutrition of the female reproductive organs are intimately dependent upon the ovary, still the fact must not be lost sight of that without the stimulus of the product of some of the other glands of internal secretion, especially the thyroid and pituitary, menstruation and therefore reproduction would be impossible. One of the fundamental ideas that has been definitely accepted in recent years is the now common one that the various endocrine glands do not act by themselves individually but by a close functional correlation through which if one gland is affected the others react very quickly in the endeavor to compensate the disturbance induced in the organism by the former. Therefore the reproductive functions are dependent upon the normal action and cooperation of the thyroid, pituitary (especially anterior lobe), and ovaries and the failure of any one of these to furnish a normal supply of its internal secretion increases the task of the rest and disturbs the normal working of the group.

Correct diagnosis must depend then upon a most careful and searching analysis of the signs and symptoms presented. By this means only can the gland primarily at fault be determined and the possibility avoided of mistaking for the real offender a gland which is but secondarily involved.

Cause of Endocrine Abnormalities.—Endocrine abnormalities may develop: (1) After any of the diseases of childhood. (2) In consequence of severe chilling. (3) Chronic debilitating diseases. (4) Prolonged puerperium. (5) Prolonged lactation. (6) Chronic cardiac lesions. (7) Pregnancy. (8) Morphine and lead poisoning. (9) Overwork and underfeeding. (10) Too much strain and monotony and too much depression.

Types.—Pituitary Type: Is divided into those in which the hypopituitarism developed in child-

*Read at a meeting of the Winnipeg Medical Society, February 18, 1921.

hood, the symptoms becoming apparent only at and following puberty, and those in which the pituitary disturbance occurred after puberty. An example of the former case is as follows: The physician is consulted by a young woman, say between 17 and 20 years of age, because her menstruation which began late stopped completely after a few irregular, painful, and scanty periods. The young woman appears to be in good health. There is a tendency to obesity. She is likely short and stocky, nose small and well shaped, perfect nostrils. Teeth well shaped, maybe some recession of chin. Hands and feet unusually small, narrow wrist, short but fragile tapering fingers. She may seem fairly bright, but upon careful inquiry it is often learned that she is inclined to be indolent and takes but little interest in school. Except that there is somewhat sparse growth of pubic hair the external genitals are normal. The uterus is found to be small. A diagnosis of infantile uterus is made and the amenorrhea and the general conditions are explained upon this basis. Clinical study of such patients, however, will reveal an increased sugar tolerance, and they are undoubtedly instances of mild hypopituitarism occurring in childhood.

The following would be an example of the latter type, i.e., the one in which the disturbance occurred after puberty. The patient gives a history of a fairly normal menstrual life before marriage excepting, perhaps, that the periods are a little scanty. Within a short time after marriage she has gradually and steadily increased in weight and at the end of a few years the increase is quite pronounced. During this period her menstruation has been less frequent and more scanty until perhaps by now there is amenorrhea. Sexually she is indifferent, and although married for years is sterile. Her expression is listless and the better defined case may complain of drowsiness. Here, too, perhaps, the physician, finding a small uterus, is satisfied to explain the entire syndrome as one due to infantile uterus, but on carefully going into the case he will find that this also is a case of hypopituitarism in which the disturbance occurred after puberty and therefore did not influence the phenomena of puberty, but found expression later in the amenorrhea, sterility, and increase in weight.

Of thyroid dysfunction the one that interests us most in relation to sterility is that of thyroid insufficiency. Here also we have to bear in mind whether the disturbance occurred before or after puberty. If it occurs before puberty the early history is most significant. Size and weight at birth, for instance, may lead us to suspect the possible influence of prenatal deficiency of the thyroid. Instead of a very large child being the pride of the obstetrician and father it would perhaps be one in which thyroid treatment should be given from the first few weeks of life. In these cases there will be late healing of the cord, late appearance or eruption of teeth, late walking and talking, mental retardation. Menses appear at an earlier age than normal and show an increase in duration and are usually free from pain. The patients are usually short and stocky, have a large head with round face. The nose is short and

blunted, with high saddling and retroussé tip. The lips are thick and full with a tendency to eversion. Teeth poorly set with a tendency to irregularity in outline and placement, especially the upper canines. Lower front teeth always overcrowded and irregular. The chin is wide and blunt. Skin is usually harsh and dry and the hair loses its gloss.

Ovarian Type: Menstruation usually occurs after fourteen years of age, is of short duration, scanty in amount, and accompanied by more or less dysmenorrhea, nausea, perhaps vomiting, backache, extreme malaise, and general distress. Genital organs well developed and secondary sex characteristics have been developed before the onset of the ductless gland disorder. There is an overgrowth of the long bones producing the unusually tall and slender individual having characteristic proportions and measurements. She has a disproportionately elongated head with sharp features, hatchet face, and receding chin. The nose is rather long, of good shape and sharply angled contour. Mouth and lips small and very thin, forming a mouth which has a tendency to be oval in shape. There is a tendency to enlargement of the upper central, and decrease in size or absence of the upper lateral incisors. Hands are long, slender, and artistic, fingers disproportionately long, narrow, and pointed.

The following are a few cases that have come under my observation during the past four years wherein results have been obtained.

CASE I.—Miss M. T., age 25 years, was first seen by me at Outdoor Clinic, Winnipeg General Hospital, April, 1920. She came complaining of amenorrhea, which was of six months' duration. Previous menstrual history was as follows: Commenced menstruating at 18, periods coming at four to six-month intervals, extremely painful, lasting about two days, losing small quantity (one napkin a day). On examination I found a well-developed woman about 5 feet 1 inch tall, weight about 140, teeth well shaped, hands and feet small, short, tapering fingers. External genitalia normal, except small amount of pubic hair, cervix elongated. Body of uterus extremely small; about the size of a walnut. Diagnosis: Amenorrhea due to hypopituitarism. She was given pituitary extract anterior lobe, grs. 2, to be taken t.i.d. This was continued for one month, when she returned stating that menstruation had come on one week after taking the tablets. She was told to continue taking the tablets, and to return in another month, which she did stating that she had menstruated again within five weeks following the last period. This was the first time menstruation had occurred so close to the last period since its onset. The patient was told to continue for another month with the tablets. Was not seen again till November, 1920, when she returned stating that menstruation had recurred monthly till two and a half months ago, since when she has had amenorrhea again. Examination revealed a uterus about the size of an eight-weeks pregnancy. When questioned as to the possibility of her having become pregnant she admitted that there was such a possibility. I then asked her how long since she was first exposed to becoming pregnant. Her reply was about two years. She was seen again in December and a positive diagnosis of three months' pregnancy was made.

CASE II.—Mrs. M. Y., age 26, called to see me on November 9, 1919, for the first time. Complaints of pain in left lower abdomen, and although married four years, has not as yet been pregnant. Menstruation regular, 28-day type, lasting two days, losing small quantity, with some backache on the first day. Had Spanish influenza in December, 1918, since which time her periods have been two or three months apart, losing larger quantity and lasting three to four days, with

backache on first two days. Last period just finished. Examination shows woman about 5 feet tall, weight 150 (has gained about 30 pounds since marriage); skin harsh and dry, teeth irregularly set and overcrowded, hair dull and without any gloss, cervix normal, uterus normal in size and position, adnexæ apparently negative. Was given thyroid extract, gr. 1, t.i.d., and told to return in one month. One month later weight was 135 (a loss of 15 pounds). Menstruation had not recurred. Was told to continue tablets for another month. When she reported again menstruation had occurred December 20 (about six weeks after the preceding period), and lasted for three days. Weight 130. Continued thyroid treatment for two months more, when she was seen again. Menses have been coming on the 28th day following last period, usual duration. Weight 125 (loss of 25 pounds in three months). Was not seen again for four months, when she returned complaining of vomiting and pain in breasts. Last menstrual period two months before. Examination shows uterus the size of a seven weeks' pregnancy. This patient went to term when she was delivered of a healthy male child.

CASE III.—Mrs. P. W. called to see me on November 19, 1919, stating that she had been married for five years and had not as yet been pregnant. Menstruation commenced at 12, was quite regular, of the thirty-day type, lasting five or six days, losing large quantities and without pain. Since marriage has been the same type. Has no other complaints, feeling in perfect health, and is quite piqued at not having become pregnant. Weight 175. Height 5.4. Has gained about 10 pounds since marriage. Examination shows uterus normal in size and position, adnexæ negative. Treatment: Thyroid extract, gr. 1, t.i.d. This was continued over a period of six months, during which time she lost 20 pounds in weight. July 27, 1920, husband called to say that his wife had not menstruated for two months—no vomiting nor nausea nor discomfort of any kind. Was told to have her come in for examination. On August 8, 1920, examination showed pregnancy of about eight weeks. Went to term and was delivered of female child of 10 pounds.

CASE IV.—Mrs. M. W., age 30, called to see me on May 24, 1917, giving the following history: Married in January, 1908, and gave birth to a full term child ten months after marriage. Since then has been sterile. Has not increased any in weight, and apart from being nervous has no other complaints. Menstruation regular, 28-day type, lasting only one day now. (Used to last three days before marriage.) Has severe pain on first two days with nausea; sometimes vomiting and dizziness on first day. Examination shows a thin woman, weighing 125 pounds, height 5 ft. 6½ inches; uterus normal in size and position; adnexæ negative. Treatment: Ovarian extract, gr. 5, t.i.d. This was continued for four months and gave relief to the dysmenorrhœa, also the vomiting and dizziness. December 15, 1918 (nearly seven months since treatment began), called to let me know that she had not menstruated for ten weeks, and thought herself pregnant. Examination revealed a pregnancy of seven weeks. Patient went to term, giving birth to a female child weighing 8½ pounds. On December 11, 1919, she was operated upon for tubal pregnancy before rupture.

CASE V.—Mrs. L. T., age 31, called to see me May 2, 1919, complaining of cramps in both hips, also between scapulae. Married seven years, and has not as yet been pregnant. Menstruates every two or three months, losing small quantity and lasting for five days; very little pain. Puberty at 14, her weight then being 145 pounds. At marriage she weighed 175 pounds; now weighs 210 pounds. Last menstrual period three months ago. Hair dull and grayish, which commenced turning at 24; eyebrows deficient at outer margins; skin harsh and dry; uterus small, cervix tapered, tubes and ovaries apparently normal. Treatment: Thyroid extract, gr. 1, b.i.d., for two weeks. May 17, 1919 (two weeks later), weight 210. Menstruated May 12, which lasted one day, then stopped for two days, and came on again, lasting two days more; small quantity. No cramps in legs nor back since. Thyroid tablets to be taken t.i.d. June 3, 1919, weight 195. Menstruated June 27 (about six weeks since last

period), lasting six days, losing a great deal; weight 185. Has had a little cramp in legs. Continue thyroid. November 10, weight 173; menstruation came on five weeks after last period, lasted three or four days, losing fair quantity. Was given ovarian extract, gr. 5, t.i.d. April 6, 1920, the patient called to see if she was pregnant; she had not menstruated for three months; weight 170. Examination shows pregnancy of about ten weeks. October 27, delivered of a male child weighing 12 pounds.

CASE VI.—Mrs. J. S., age 28, was seen for the first time by me on September 29, 1916. Complaints of pain in left lower abdomen, one week before and one week after menstruation. Married eight years; never pregnant. Had a dilatation and curettage done for sterility two and a half years ago. Menses every six weeks, lasting three days; pain as above, losing fairly large quantity. Weighted 150 pounds before marriage; now weighs 182. Height 5 feet 7 inches. Examination shows uterus normal in size and position, adnexæ apparently normal. Treatment: Thyroid extract, gr. 1, t.i.d. This was continued over a period of four months, which brought her weight down to 162 pounds and her menstrual periods to the regular monthly type. May 15, 1917 (nearly eight months later), has not menstruated for three and a half months. Complaints of pain between shoulders. Examination shows pregnancy of about three months. May 24, 1917, aborted a macerated fetus of about two and a half months; placenta retained, which was removed manually under an anesthetic. June 26, has not menstruated since miscarriage. Was given ovarian extract. December 17, 1917, called to say that she had menstruated on June 30 (four days after taking ovarian extract), then July 24, and not since. Examination shows uterus size of four and a half months' pregnancy; felt fetal movements three weeks ago. She went to term and was delivered of a baby girl, 8 pounds. Has since then had another full term child.

CASE VII.—Mrs. W. M. S., age 37, was first seen by me on September 21, 1917, complaining of severe pain in lower abdomen and back on the first and second day of menstrual period; also nausea and vomiting. Married fourteen and a half years; three pregnancies. Last pregnancy nine years ago. Menstruation regular, of the 28-day type, lasting two or three days, but scanty. Before last pregnancy periods used to last four or five days, losing large quantity, and without pain or vomiting. Examination showed a woman about 5 feet 8 inches in height; weight 130 pounds. Pelvis apparently normal, except for a slight laceration of the cervix, which was slightly everted. Treatment: Sodium bicarbonate douches and ovarian extract, gr. 5, t.i.d. After taking the ovarian extract for three months the dysmenorrhœa disappeared, also the nausea and vomiting. The periods lasted for four or five days and were more profuse. March 15, 1918 (about six months after first coming), called to say that she had not menstruated for two months. Examination showed probable pregnancy. This was later verified, and she went to term, giving birth to twins after not having been pregnant for nine years.

CASE VIII.—Mrs. E. G. Dana, Sask., age 22, called to see me on September 17, 1918, complaining of discomfort in epigastrium which had no relation to taking of food. Married four years. Has not as yet been pregnant. Has gained 50 pounds since marriage; now weighs 180 pounds. Height 5 feet 3 inches. Menses before marriage always regular, but now very irregular, the patient going from two to six months without menstruating. Last period March 19, 1918 (six months ago). Examination shows an excessively fat woman, with flabby, fat abdomen, cervix tapering and long; body indefinitely felt and unable to determine its size. Treatment: Thyroid extract, gr. 1, t.i.d. October 18, 1918 (one month later), wrote saying she had not menstruated. Weight 168 pounds. September 3, 1919 (one year later), came to consult me again. Her weight is now 150 pounds, and she has menstruated regularly every month since November, 1918 (i.e. after about two months' treatment), and wants to know why she has not become pregnant. I gave her ovarian extract, gr. 5, t.i.d. November 2, 1919, she wrote saying she had not menstruated since September 12, 1919. April 13, 1920, she wrote again, saying she felt fetal

movements on January 25. Went to term and gave birth to a male child weighing 10 pounds.

CASE IX.—Mrs. A. J. S., age 36, came to Winnipeg General Hospital Outdoor Clinic last July, wanting to know why she had not become pregnant. Married five years. No previous illnesses except an amputation of the left leg above the knee at 15 years of age, following an accident. Menses regular, lasting two days; pain and vomiting on first days, losing small quantity. Examination showed a tall, thin woman, weighing about 110 pounds, with sharp, pinched features and long, thin hands. Teeth good; upper laterals missing. Pelvis normal. Was put on ovarian extract, gr. 5, t.i.d., which she has been taking continuously since then. Called at my office on the fourth of this month, complaining of nausea and vomiting, pains in the breast and frequency of micturition for the past ten days. Has not menstruated since December 2, 1920. Examination shows a uterus the size of a seven weeks' pregnancy.

I have already exceeded my time limit, therefore will not go any further, although I have about fifteen more cases of sterility that I have been able to obtain results in by using the organic extracts. Kindly accept my apology for keeping you beyond the allotted time and I will close by quoting an extract from a paper by Williams on organotherapy.

"Yesterday was the day of the pathologist, more especially of the bacteriologist. The day before yesterday witnessed the triumphal progress of surgery. Physiology and medicine, all wrung in the withers and quite chapfallen, contented themselves, perforce, with the crumbs that fell from the rich microbic tables of these others.

"But the whirligig of time brings in his revenges. To-day, to-morrow and the day after, are foreordained to the physiologist, the physician, and the therapist. Their hour has come through the agency of the internal secretory glands, which already unfold before the astonished view of the seeing eye a land of promise, beside which the vast territories conquered by Lister and Pasteur, are destined to pale into honorable insignificance.

"The ductless glands and their hormones come to us as peaceful conquerors who brook no denial. They lighten our darknesses and show us apparently miracles. In studying them and endeavoring to unravel their intricate and esoteric mysteries, one seems ever and anon to be on the trail of the 'Great Secret' and in danger of losing one's mental perspective."

405 BROADWAY.

INSANITY;*

A BROAD RÉSUMÉ FOR THE GENERAL PRACTITIONER.

By SIEGFRIED BLOCK, A.M., M.D.,

BROOKLYN, N. Y.

IT is of much interest to every medical man to review a subject which is at present increasing to such a degree that the statistical figures are astounding. I will not burden you with numbers but in the short space of time allotted will go directly to the matter at hand for consideration. We must first of all remember we are talking only of abstract affairs of the mind. We are dealing with thought, judgment, reason, etc. All of these things

*Read at a meeting of the Northern Brooklyn Medical Society, January 25, 1921.

cannot be passed upon unless we take into account the education of the individual and the environment in which the patient happens to live. The age, heredity, previous life, etc., must also be carefully studied before a proper diagnosis can be made.

To recall briefly a few terms which are used in psychiatry mention must be made of:

Delusion. This term is used to describe a perception of one of the senses which is distorted. For example, seeing a chair and believing it to be a man or some object not a chair, or hearing a bird sing and believing it to be a human voice, etc.

Hallucination. This term is used to describe a perception when there is nothing to perceive, as hearing strange voices when no one is present to make the sounds; or seeing apparitions, etc.

Imperative conception. This term is used to describe a conception which the patient knows to be false but nevertheless cannot put it out of his mind. If he does not know it to be false, it of course becomes a delusion.

A *morbid impulse* is a desire which the patient cannot resist carrying out. As a wish to run away from home, or a desire to steal, set a house on fire, etc. An imaginary illness must not be confounded with a functional disorder which is not imaginary but genuine.

Among the most common functional mental disorders are: Hysteria, neurasthenia, dementia precox, manic depressive insanity, paranoia, paresis, senile dementia, etc.

It is unnecessary to dwell at length on hysteria, except to state it is a functional, but genuine, and not an imaginary disease. The same may be said about neurasthenia. These two conditions were discussed here in a previous communication and we may dismiss them without further mention.

Dementia precox is a form of insanity coming on usually but not necessarily in the earlier part of life. The previous history of these patients often shows that as children they were a little different from other children of the same family. They may have been especially bright or affectionate. They usually give a history of a shut-in personality, preferring to stay alone and reading to going out and seeking the company of playmates. They are often bashful and backward socially. Many of these are more religious than their brothers or sisters, etc. As time goes on they get into a rut so to speak, and usually after a severe mental exertion more marked symptoms come to light. Sometimes in a well-developed case the person will talk in a wild disconnected way. The short sentences, the dissociated phrases, the wild flight of ideas are an indication of the working of the mental apparatus. The actions may be of the same nature as the words expressed. In another class of cases the patient talks very little or not at all. One of this type may sit for hours in a corner, apparently listless, eating and drinking nothing, soiling his or her clothing, etc. On examination we find these patients very stubborn; they refuse to obey any command given them. Some even do the opposite of what is asked of them. As, when asked to open the mouth they will close it; or, when asked to sit down they will stand up, etc. This phenomenon is characteristic of this type of insanity and is called negativism.

With all these symptoms the memory and in-

sight of the patient into his mental state seems to be good. The more sudden the onset and the more the patient is of the second type of case mentioned the more likelihood is there of recovery. In most of these cases there is no history of any hereditary taint in the family.

Some of the cases go on to a complete dementia but only late in this disease do any memory defects occur. Memory for more recent events is lost sooner than memory for old and remote affairs of one's life. A peculiar condition occurs in these cases, especially in the second type mentioned. That is in the quiet, apparently listless patient at times a tendency exists to leave a limb or a part of the body in any position it is put. This is termed catatonia. All degrees of catatonia may be present from merely sitting in a peculiar position for hours to staying for almost an indefinite period in any awkward attitude in which the patient may be placed. There are patients who talk of peculiar sex or love affairs, of being under certain spells, such as electricity, which is being used to influence them, etc.

The catatonic types get well almost without exception, while the paranoid, the first type mentioned, usually do not recover. Hallucinations almost never occur in this form of insanity.

These patients are at times very impulsive. Without any previous warning they will often commit some act which is perhaps dangerous. Thus they may suddenly strike some one or throw some object, and then continue what they were doing before in a calm way as if nothing at all had happened.

Paranoia, or doubting or delusional insanity, is a type of disease which is characterized chiefly by the delusions present. The patients have delusions which often become so firmly fixed in their minds that one cannot eradicate them. Often these delusions become what is called systematized; that is, in order to prove in a reasonable way why a certain train of thoughts is in the patient's mind he will argue perhaps from false premises and therefore naturally draw wrong conclusions. A patient's line of reasoning may start from a dream and as time goes on all the intricate ideas that confront one in life may become mingled into the dream. If these delusions are actually believed true by the patient, and especially if he reacts to them and tries to make others believe the same way, he is suffering from paranoia. For example, a man may state that he believes that he should own all the oil wells in the world. He will tell you that his great grand uncle was the only brother of the discoverer of the first oil well and he being the only living person in direct line of descent, naturally he should own all the oil wells; he may go into minute details and produce figures to prove his points. These patients become very dangerous, often, because nothing can stop them from carrying out their belief and they may commit crimes to further their cause. If some one opposes them they become his enemy. If they see this enemy talking to some other person they often think that the subject of the conversation is against the patient and thus many suspicions and jealousies are aroused. They always talk about conspiracies, schemes. They are often the leaders of peculiar sects, religious and

otherwise. They are not the so-called religious fakers but genuine believers. They are fanatics, monomaniacs. Many of them are very dangerous and well advanced cases will stop at nothing to carry out their distorted ideas.

Sometimes they know they are suspected of irrationality and very cunningly hide their pet hobbies. In cases of this type it takes quite some experience and ingenuity to bring out the hidden thoughts. They remember the smallest details to prove their thoughts to be true. Such matters as dates, small points about certain glances of a supposed enemy, an insignificant act, and the like may be in the patient's mind for years. Add enlargement of the productive imagination of such a patient to any of these, boil them up with time and irritation, or other resistance mental or verbal or physical, and behold, what must one expect? Paranoiacs are the most dangerous of all kinds of insane and must be very cautiously handled.

As in all types of mental disease varying degrees of the illness exist, and these must be properly weighed before a question of danger to the patient himself or others can be passed upon by the examiner.

Paresis, sometimes called softening of the brain, is always the result of syphilis. Among the first evidences we have of this disorder is a marked coarse tremor of the hands, face, lips, or tongue. The finer movements of coordination are interfered with so that speech is not clear, especially when certain difficult phrases or sentences are attempted. Among the phrases used are "Fifth artillery brigade," "Around the rugged rock the ragged rascal ran," "Emancipation proclamation" and many others. These cases often present a history of syphilis, give serological specific tests, show an increased cell count in the spinal fluid, have irregular pupils or pupils immobile to light, etc. They may present a Romberg sign or lack knee-jerks. The blood at times shows a positive Wassermann in some of the cases. In some only the spinal fluid shows syphilitic signs. This type of case often goes along unnoticed until suddenly an act of great irrationality is performed, such as drawing a life's savings from the bank and buying some useless thing with it; ordering articles two or three times over; suddenly taking to a new and foolish habit from which one has previously been free; doing some act of gross immorality or indecency, etc. These patients become progressively worse and finally die mental derelicts. In a few cases with vigorous antispecific treatment amelioration of the symptoms take place and apparent cures are performed. But these are only of a temporary nature, and the final breakdown comes inevitably.

The term Manic Depressive Insanity is used to define a peculiar condition in which the patient is either markedly depressed or in the reversed condition, which may assume the form of a wild mania. All degrees of this state exist, from a mild melancholia to a state of self-accusation and great desire for self-destruction. Extreme moroseness, unhappiness to a degree which no normal mind can conceive, makes these patients objects of great pity. They often have an insight into their condition and beg for help. At times some of them in the more advanced types of cases ask to be left alone so that

they can take poison and end the horrible torture. Often they claim to have committed an unpardonable sin or crime and keep praying for days, weeks or months without stopping except for exhaustion.

In contrast to this class of the depressive type we have an exalted type. Here we find all degrees from a mild euphoria to a wild mania, in an advanced case. The patients will talk irrationally for hours; will fight any attempt to restrain them from doing what they wish. They will wander away often without any goal in view. They seem to have lost all judgment and the power of curbing their desires. They ramble from one subject to another, often not finishing a sentence. Hallucinations and delusions are quite common. At other times these ideas follow a trend somewhat like the paranoias but they are not so deeply or positively set into the foreground of the mental picture as in the former mental disease. The prognosis in these cases is nearly always good but recurrences usually take place. In many of these cases the succeeding attack may be different from the previous one. For instance, a manic attack may be followed by a period of gradual restoration to health, and this in turn by depression. In other cases the following attack may be a manic after a previous manic or a depression follows a depression. In any of these types there is the possibility of a period of normality of a duration which may be days or even many years. In one form, called *circular insanity*, there is practically no period of health and a depression alternates with an excited attack regularly.

These cases usually give a history of heredity upon which a severe mental shock has been engrafted. A death in the family, a financial loss, a prolonged illness, or other mental strain may be the exciting cause.

In conclusion we must not forget that so many of these mental states do not affect the memory or the patient's insight into the state; especially in marked catatonic states the attending physician is tempted to believe that the patient does not know what is going on about him. It is in this kind of case that one must use great tact and diplomacy, because when the patient is again normal he will come back with reproaches that are, to say the least, very embarrassing.

A second point to remember in these cases is that when the patients are cured their full rights as citizens are reestablished; if anyone divulges any professional secrets the patients are quick to come back with justifiable suits. A third point to remember is that certain types are dangerous not only to themselves but to their fellows, and whatever the inexperienced family may wish, they must be advised of this danger. This is especially true of certain dementia precox types.

A fourth type comprises those who suffer from a complex as it is called—a dissatisfaction which might perhaps be cleared up sometimes at home, at other times in a hospital.

A fifth point to think of is that what the patient says and what the patient thinks do not always correspond.

A sixth point to remember is that where no mentality existed no mind can be lost. The idea is that feeble-mindedness and insanity are two different illnesses and must not be confounded. Hence we

must be very careful in judging children insane.

The following is a summary of types of the insanities mentioned:

CASE I.—A young school teacher, who as a student was always the head of her class, taking all the prizes right through the elementary and high schools, was referred because she did not care about her school work any more. She had not been at her class in four weeks, choosing to remain in bed and simply answering "because" to any question asked of her. At times she would be quite rational and gave evidence of a good memory for both recent and remote events. She knew everyone about her, but seemed to take very little interest in what they did or said. Her sense of shame was grossly lacking. She cared very little whether her body was exposed at the examination or not. When her arms were extended by the examiner she left them in the position for four or five minutes before she would take them down; and then only slowly. On two occasions she soiled the bed with feces. Her sister claimed that for a long time her underclothing would become quite filthy after her bowel evacuations, although no one ever remarked about it. The toilet seat also would not be left as clean as might be after she finished using it.

The only thing of interest bearing on this case in her past history was that she never went out with other girls, but always remained at home and studied (shut-in personality). Another point bearing on the case is that about one month before she stayed in bed, while at the moving picture show with her mother, for no reason at all, not even an argument, she suddenly slapped her mother in the face and then went on looking at the picture as if nothing at all had happened (spontaneity). The mother was embarrassed and went home, but the girl remained to see the whole performance and came home as unconcerned as if nothing strange had happened.

She could not be treated at home; was committed to a State hospital, and has now returned and is teaching again. The whole case represents a quite typical dementia precox of the catatonic type, with apparent recovery.

CASE II.—At one of our institutions the secretary to the superintendent suddenly began to become loquacious. She would talk without stopping for hours at a time. The conversation was disconnected and rambling. Occasionally she would stop to talk about the woman in the next house, who would turn on the "current" through the walls, etc. This was the evil influence that made her "crazy," she would cry out loud. This girl also gave a history of shut-in personality. She had no catatonic phenomena. Her parents remarked that she had not been sleeping well of late and that she seemed to talk about an electric current of a neighboring house for several months. They never paid much attention to it. As a child she was always different from the six other children. She always asked to be dressed rather gaudily. She would be late for her meals, was disobedient, and was a very difficult child to bring up in comparison with her brothers and sisters. The onset was three years ago and she has not improved much. She now soils the bed and clothing regularly. She has become very negativistic and must frequently be tube-fed. She has lost a great deal of weight, hardly recognizes any members of her family except to call their names, say "Hello," and then go on talking in an aimless way. This is quite a typical case of the second type of dementia precox mentioned. Cases of this kind are usually incurable. They often die from an intercurrent disease. Many seem to be susceptible to chest diseases such as pneumonia and tuberculosis.

CASE III.—To illustrate a case of paranoia one might mention the woman of sixty who was arrested on the steps of City Hall for gathering a crowd and preaching without a permit. She was given a summons and asked to appear before a certain police magistrate for breaking a city ordinance. When she appeared at the bar she spoke of the outrage of arresting her when God had given her the right to go among the people and show them their errors and try to make them follow the teachings of Jesus Christ. She claimed to be "inspired," and no man had a right to interfere with

her work. She could not be reasoned with at all. The magistrate lost his patience and sent her for observation into her mental condition. During the investigation it developed that she had a host of faithful followers in another city. Although she never definitely said she would harm anyone, all the examiners felt if opposed strongly she would feel "inspired" to do anything to fight for God. Take a life if need be. She is very tractable, but when one talks to her on any subjects touching on her delusions she is off on a wild tantrum. She remembers every word in the argument with the magistrate. Small details in regard to her arrest and incarceration are always at hand. This is quite a typical case of paranoia. This patient has never tried to hide her delusions, but it is to be expected in an effort to gain her freedom she will for a time with much effort not mention this religious trend of her thoughts, and ask to be examined, thus proving that she is now well again. If it is a concealment that gains for her the desired freedom she is likely to come back at some time and work out her vengeance on the "enemy" to her work. If she really feels "inspired" there is no telling how far she might go.

CASE IV.—An interne in a regular hospital came home to tell his uncle, who is a physician, that he (the interne) could now cure any kind of an illness. He then went back to his place at the hospital. Not very long afterward he was found beating up a drug clerk and the next day he claimed to have wonderful muscular power and he could whip anyone. He threatened to throw the examiner off the roof. He made all kinds of statements, most of which were disconnected and in no way associated with his examination. He wrote pages of letters in the same tenor. In the next twenty-four hours he became so unruly that he had to be restrained. In three months he was absolutely cured.

His family history is that his father and his mother both have insane members in their family. His paternal and maternal relatives all have manic depressive members, some of whom are or were in hospitals and others have been treated at home. The writer has treated four such members himself. This is a typical excited manic case.

CASE V.—The uncle (not the doctor) of the preceding was of a typical depressed type. He became very morose, and claimed that a girl to whom he was engaged to be married had broken the engagement because she found out he had a very serious and contagious sexual disease. This was untrue. The girl never broke off the engagement. He began to pray and entreat God for pardon of his misdeeds. He often said he wished to end it all. How did he have a right to live with such shameful knowledge of himself. This was a hallucination, for he never had any sexual disorder of any kind. He would chide himself for taking up this girl's time, etc. His plight was a very sad one. In six months this man was seemingly quite well again. He is back in business again doing serious work and supporting his widowed mother. He remembers the whole episode distinctly, and describes it as horrible.

Although both he and his nephew are quite well now, they are liable to get other attacks. Of course they must not be told this fact or they will not feel free to act as healthy individuals.

CASE VI.—To briefly describe a typical case of paresis we need only take a man who owned a candy factory and one day ordered so many small candy boxes from a manufacturer of paper boxes that suspicion was at once aroused. The next day this man ordered several thousand dollars' worth of chrysanthemums to be planted in his yard and each flower was to have a small electric light in its center. Examination showed that he had seventy-nine cells in his spinal fluid and this fluid showed a four plus Wassermann reaction. The blood test was negative. His speech became more and more indistinct. He had marked tremors, coarse and fine, of his tongue and hands. He deteriorated very rapidly, lost all sense of propriety, and died two years after losing the peculiar order for boxes.

It would be unwise in a paper of this kind to mention more than a single case of each kind to give a broad view of this subject. Thus can a general practitioner get a formula, though crude, that he

may follow to appreciate that insanity is a quite definite science. That it is important to be able to give a prognosis as well as a diagnosis not only for the patient but also for his family and business associates.

502 WASHINGTON AVENUE.

UROLOGY: ITS PLACE IN MEDICINE.*

By H. W. E. WALTHER, M.D., F.A.C.S.

NEW ORLEANS, LA.

THE advances made in urology in the past decade have more than justified its claim to a prominent place among the major specialties of medical practice. The progress achieved has been deliberate and epoch-making in character.

The perfecting of the armamentarium of the genitourinary surgeon has aided to no small degree in placing his work upon a scientific basis. With the cystoscope, both operative and diagnostic; the prism urethroscope; the ureteral catheter; the various operative instruments for intravesical and intraurethral manipulations; and by the combined efforts of the x-ray tube and the opaque ureteral catheter, many hitherto impossible procedures of diagnosis and treatment can now be carried out with comparative ease.

A visual study of the lower urinary tract with the cystoscope and the urethroscope gives definite information that cannot be obtained by any other means. Then, in urinary infections, to catheterize the ureters and collect the separate kidney urines for study will give undisputed data as to which kidney is the offender.

However brilliant may seem the advances made in perfecting instruments and appliances that he daily employs, the urologist points with still greater pride to the strides made in the study of renal function, particularly as relates to phenolsulphonephthalein and indigo-carmin as tests of the secretory power of the renal tubules. Then, too, the clinical application of the blood-chemical methods for determining retention products, as nonprotein nitrogen, creatinine, etc., were for the first time placed on a practical working basis by urological investigators.

Now as regards the application of these methods to general practice. Let us take the most common symptom for which a patient, suffering with a supposed urinary complaint, consults us. I refer to *frequency* and *burning*. The first condition that the average practitioner thinks of is Neisserian infection. But supposing the case proves negative for gonococci. Some other bacterium, such as a coccus or a bacillus, may be found. Or the urine might show only a sterile pyuria, as is particularly frequent in renal tuberculosis. Supposing further that the ordinary measures employed for treating cystitis fail after a reasonable trial. What then?

It is contended by the majority of urological workers that primary inflammation of the bladder is comparatively rare; that cystitis is usually secondary to infection of one or both kidneys. Exceptional cases may be encountered where the bladder mucosa has been traumatized by a dirty catheter or where the viscous harbors some foreign body, as a

*Read by invitation before the Lafourche Valley Medical Association, Thibodaux, La., February 15, 1921.

calculus, serving as an irritant. Here then would be a case where cystoscopy and ureteral catheterization are indicated. Let me illustrate this type with a case-record:

CASE I.—A woman, thirty-two years old, recently consulted me because of marked urinary frequency—both nocturnal as well as diurnal—and ardor urinae. The trouble had persisted for three months without relief. Her family physician told her she had "cystitis," and gave her urotropin by mouth and a weekly bladder instillation of 10 per cent. argyrol. Under this treatment she did not improve.

Upon her consulting me, I immediately cystoscoped her, catheterized her ureters, and collected from both kidney pelves a urine loaded with pus cells and colon bacilli. Both renal pelves were lavaged with a 2 per cent. silver nitrate solution. Relief was almost immediate. The day after the first lavage she phoned me that she had slept the night through—the first time this had occurred in three months. Four lavages cleared up the infection in the kidneys and after the second treatment the intervals of voiding had returned to normal, that is, three times during the day and not at all at night.

It is not such a long time ago that surgeons would occasionally be faced by a sudden death following a nephrectomy or even after a simple cystotomy, and the fatality was not easy to explain. Yet were the operator so fortunate as to obtain an autopsy in such cases he would have invariably found that, in the nephrectomy case, he had removed the only functioning kidney; and in the cystotomy death it would have been equally well shown that both kidneys had suffered marked embarrassment from prolonged damming-back of foul urine upon the kidneys—a condition due to back-pressure of an hypertrophied prostate or of a urethral stricture. The shock of rapidly evacuating over-distended bladders, particularly in old men, may produce anuria or gradually lead to uremia from which the patient does not rally. Two case-records will illustrate this point:

CASE II.—A negro male, seventy-three years of age, was admitted to a charitable institution late at night suffering from urinary retention. He had not voided in several days. The bladder fundus could be felt on a line with the umbilicus. A resident surgeon attempted to pass, in succession, a soft-rubber catheter, a metal catheter, and lastly a steel sound, but without success. All instruments used were of the size 25 F. Because no filiforms, Le Fort instruments, or other aids used in surmounting strictures were handy, the surgeon did a suprapubic cystotomy, emptied the bladder completely, left in a Pezzar catheter above and returned the patient to the ward. During the next twenty-four hours the patient passed only an ounce of urine and the next night died. Here one has exemplified the fatality that occurs from shock, due to sudden emptying of the bladder, which is followed by anuria and death.

CASE III.—A white male, seventy-six years of age, was admitted to a hospital, also suffering with urinary retention. In the course of a routine urological examination, the prostate was found markedly enlarged by rectal palpation. Cystoscopy confirmed the rectal findings. Patient was put to bed and kept warm. A soft-rubber catheter, threaded over a curved wire mandrin, was passed into the bladder, was fixed in place with adhesive tape to the penis, and about 500 c.c. of urine was drawn off every two hours, until bladder was empty. By this gradual evacuation, no alarming symptoms developed. The catheter was allowed to remain in place. The bladder was irrigated daily with 2 per cent. boric acid solution. At entrance the phthalein test read 14 per cent. for two hours; urea nitrogen 97 mg., and creatinine 3.8 mg. for each 100 c.c. of blood. Within ten days of catheter drainage the phthalein rose to 38 per cent. in two hours; urea nitrogen 24 mg. and creatinine 2.9 mg. for each 100 c.c. of blood.

Suprapubic cystotomy was now done under local anesthesia without disturbance to the patient. Pezzar catheter drainage was established suprapubically; urethral catheter (which was producing marked urethral spasms and irritation) was removed. Within twenty days after entrance the phthalein reading was 45 per cent. for two hours; urea nitrogen 14 mg. and creatinine 2.1 mg. for each 100 c.c. of blood—practically normal findings for a man of his age. Prostatectomy was now carried out suprapubically under light ether-gas-oxygen anesthesia. Recovery was uneventful.

Hematuria is a symptom that, when present, deserves our most serious consideration. Although of not extremely common occurrence, its presence may be the only warning sign of cancer somewhere in the urinary tract. Therefore we should adopt the rule that *every case of hematuria demands immediate cystoscopy* in order to determine the source of the bleeding. The routine practice of the attending physician passing over hematurias lightly, of administering some internal medicine and sending these patients "on their way," is a practice that cannot be too severely condemned. Another case-record here will illustrate what I mean:

CASE IV.—A white male, sixty-three years of age, consulted me not long since for severe pain in the bladder region, marked frequency and the passing of bloody urine. He had had intermittent attacks of hematuria for the past fifteen years! And all of this time he had been under the care of one physician or another. He had taken medicine by mouth until he had become disgusted with drugs. Cystoscopy revealed a vesical carcinoma occupying the entire left lateral wall of the bladder and trigone region. Marked, irregular, intravesical projection of the prostate was also seen. Upon rectal palpation, cancerous metastasis to the prostate was definite. This case had progressed until now it was beyond relief. For humane reasons suprapubic cystotomy was performed under local anesthesia, and this gave him much relief from pain. He lived six months after I saw him.

Pain probably brings more patients to the physician than any one other symptom. And how often is it the case that in vague abdominal disorders it is practically impossible to differentiate, let us say, appendicitis from right-sided ureteral stone or tubovarian trouble; or again, to say definitely whether or no a pain in the upper right quadrant of the abdomen is due to gall-bladder trouble, renal calculus, or a ptosed kidney with a Dietl's crisis. Or looking at the matter from another angle, admitting that the trouble is renal, how can we say that the painful side is the truly diseased one? We know that cases exhibiting *renorenal reflex* phenomenon are met with every now and then. The clinician is told that all the pain is in one side but finds all the pathology in the opposite side. In any of these instances cystoscopy, ureteral catheterization with opaque catheters, and the making of pyelograms become almost imperative. With either the wax-bulbed ureteral catheter or x-ray films or by combining the two procedures, ureteral calculi can be definitely diagnosed. By renal catheterization and the taking of pyelograms the diseased side can be recognized and in the radiogram we can note the abnormal misplacement of the kidney, if such exists. I desire to report briefly, as illustrating renorenal reflex pain, the following interesting case:

CASE V.—A young white female fourteen years of age, was brought to us suffering with intense pain in her right side. As her physician had repeatedly found albumin in her urine for over a year he had considered

the case one of chronic nephritis. Of late the patient had been developing attacks of extreme pain in her right side, high fever, marked urinary frequency, and hematuria. Cystoscopy and ureteral catheterization demonstrated a normal right kidney as shown by the urine chemically, microscopically, to culture, and by functional tests. The left kidney urine showed a heavy albumin deposit, many pus cells, many cocci and bacilli, many red-blood cells, a much reduced renal function, and radiograms revealed three calculi in this left kidney. Radiogram of right kidney negative. Left nephrolithotomy, followed by a few lavages of the left renal pelvis (to rid it of infection) produced a complete cure. The pain in the right side disappeared the day following operation and has not returned.

Sexual disturbances, particularly in relation to impotence in the male, not infrequently bring patients to the physician, seeking relief. Derangements of genital function often tax the acumen of the clinician to the utmost. That with some of these patients the trouble is only imaginary is perfectly true. That some, however, suffer with true sexual neurasthenia or some functional neurosis is equally true. Practising psychology helps many of these cases. With another group we must go further.

The posterior urethra, particularly the verumontanum, plays a very important role in many cases of disturbed sex function. With the increased interest shown by urologists in more universally employing the posterior urethroscope in studying these cases, better results can be expected in the future. Where inflammation of the verumontanum exists, treatment in the form of instillations, topical applications, or high-frequency fulguration to the affected part most frequently accomplishes the desired result.

Radium therapy is being extensively employed in urology in such conditions as are deemed appropriate. And whereas it has proved disappointing in many cases, in other selected instances it has accomplished much good. The mere fact that it has a selective action only on certain tumor-cells renders it of more value in some cases than in others. For instance, in cancer of the prostate, seminal vesicles, or the external genitalia it seems to retard the process slightly. But such retardation is only transient. It does however control pain frequently and minimizes hemorrhage. In early bladder carcinoma the results from radium have been more promising. In papilloma of the bladder or urethra it is almost a specific. Much experimental work is still necessary to determine the exact value of radium in urology. Whether the combination treatment with x -ray, or with high-frequency fulguration, or the employment of all three agents conjointly, namely, radium, x -rays, and high-frequency fulguration, will give the best results, is one of the many problems in medicine still to be solved.

In conclusion, it is submitted that urology, as a surgical specialty, has won for itself a very definite place among the medical sciences. That by the general practitioner utilizing more liberally the many aids that the urologist has at his command, correct diagnoses will be made more frequently, the administering of proper treatment will be instituted with more dispatch, and our percentage of invalids and incurables among those suffering with genitourinary ailments will be reduced to a minimum.

MACHECA BUILDING.

A CASE OF CHRONIC NEPHRITIS WITH A RENAL NEOPLASM.*

BY CHARLES GREENE CUMSTON, M.D.

GENEVA, SWITZERLAND.

PRIVATE DOCENT AT THE UNIVERSITY OF GENEVA.

ERRORS in diagnosis and surgical surprises in practice should always be recorded, hence the following case history:

Male, aet. 47 years, was seen in consultation in view of performing renal decapsulation for advanced chronic nephritis, a survival of some weeks being desired on account of business interests.

The patient's history was devoid of interest until 1909, when he first noticed some transitory malleolar edema, rather frequently recurring epistaxis and some headache. However, these symptoms did not increase in intensity, so that the patient was able to continue his affairs until the middle of November, 1919, at which time he developed paroxysms of dyspnea lasting for some twenty minutes to half an hour and recurring once or twice a week. By March, 1920, these so-called "asthmatic attacks" became more frequent and severe, and at length the dyspnea was constant night and morning. There was also intense headache and much lassitude. Patient micturated two or three times in the night.

On May 13, 1920, when we saw the patient, the following notes were taken: marked dyspnea, face slightly puffed with pale color peculiar to chronic renal disease. Temperature 36.9° C. (98° F.).

Circulatory system. Pulse regular, weak, high tension, 100 to the minute. The heart apex could be indistinctly felt under the sixth rib; no vibration or thrill, but by palpation one could feel a general rising of the thoracic wall. On auscultation the first sound was distant and prolonged with accentuation of the second sound. The aorta could be felt in the suprarenal fossa, but not in the abdomen. The femorals were hard, tense with strong pulsations, but did not appear to be enlarged. Blood pressure with Vaquez's sphygmotensimeter = 18 maximum. Blood examination, hemoglobin, 73 per cent.; red blood cells, 3,950,000; white blood cells, 11,960; globular value, 0.92; polymorphonuclears, 79 per cent.; lymphocytes, 12 per cent.; mononuclears, 7 per cent.; eosinophiles, 2 per cent. Dosage of urea in blood, 1.95 per liter; indican absent.

Examination of the lungs and nervous system was entirely negative. Examination of the eyes revealed albuminuric neuroretinitis, more pronounced on the right.

Digestive system. Tongue clean, no dyspeptic symptoms. For the week after examination there was nausea and easy vomiting of food. Abdomen somewhat distended, no muscular rigidity, no dull area. Liver and splenic dullness normal in extent.

Urogenital system. Micturated several times in night and five or six times during the day. Some burning at the end of the act. Lower pole of right kidney could be palpated. Left kidney could not be felt. Prostate normal, seminal vesicles not enlarged. Permeability to methylene blue maximum delayed, low elimination lasting six days. Total amount of urine in twenty-four hours, 2,250 c.c. Examination of urine, clear, transparent, no shreds, slight flaky sediment after standing. Albumin, 2.3 per liter; glucose, guaiac test, bile pigment, biliary acids and urobilin were negative; urea, 15.5 per liter; chlorides, 2 per liter. Microscopically, there were some large opaque granular casts, some free kidney cells and an occasional leucocyte. No red blood corpuscles were found. To complete the examination a Wassermann test was made on the blood and cerebrospinal fluid and proved to be negative in each.

The diagnosis was chronic nephritis, renal heart and pericarditis.

Given the patient's status and the clinical data ob-

*Read at the annual meeting of the Section of Urology, Royal Society of Medicine of London, May 27, 1921.

tained I was most disinclined to do decapsulation, more particularly on account of the extremely slow and imperfect elimination. However, as the patient and family were very insistent, I acquiesced.

On May 20, 1920, the right kidney was exposed, the lower pole being detected at the bottom of the incision and moving freely with the respiration. Introducing the hand to free the upper pole and to bring the organ out of the incision, a tumor the size of a large orange was found to occupy the upper pole. After breaking down a few friable adhesions the kidney was delivered without too much manipulation. The neoplasm was round, distinctly confined to the upper pole, whitish in color and firm to the touch. Given the circumstances decapsulation of the lower pole of the kidney was quickly done and the organ returned into its fatty capsule. The left kidney, which was very shrunken, was decapsulated without too much difficulty.

The outcome was much more simple than might have been expected. Operative convalescence was uneventful. The dyspnea and headache were considerably ameliorated but the urine continued to contain albumin and casts in the same amount as before the interference. The patient survived exactly five weeks, dying in uremic coma. One week before death the urea in the blood had increased to 2 grammes, 65 centigrammes per liter. Perhaps, in this case, decapsulation may have accomplished the end for which it was done, namely, to postpone the fatal outcome for a week or two, but it certainly did not hasten it.

The renal growth, obtained post mortem, proved on histological examination to be an adenoma and both kidneys were the site of atrophic nephritis.

Primary renal neoplasms arise either in the capsule or in the pelvis of the kidney and are either non-malignant or malignant. According to the degree of malignancy the malignant growths are divided into cancerous and sarcomatous tumors. The former belong to the epithelial type and include but one variety, namely adenomata. These neoplasms are often consecutive to nephritis and may be overlooked clinically, while in kidneys manifestly involved by interstitial nephritis one or several gray or reddish nuclei, varying in size from a pin's head to a filbert, are found directly under the capsule.

On the contrary, in adenomata strictly speaking, the kidney appears normal. Single or multiple, the growth is usually directly subcapsular—it may, however, occupy the medullary region—not usually larger than a cherry and offering a yellowish-white color. The capsule is usually thick, separating the growth from the renal parenchyma, while the white tractus given off by the capsule divides the neoplasm into distinct lobes.

The symptomatology of these tumors is reduced to two cardinal symptoms, namely, tumor and hematuria, while pain becomes added later on. In 50 per cent. of the cases hematuria is the first symptom noted, but it may occur tardily in the evolution of the neoplasm at a time when the latter has attained notable proportions. However, in the case here reported no red blood cells were ever detected in the urine. This hematuria occurs without any evident provocative cause, gives rise to no painful phenomena, lasts for two to four days and then subsides only to recur in a few weeks or months. The amount of blood voided varies greatly from one case to another. Lastly, instead of a frank hematuria, the loss of blood may be only microscopic, but this can usually be detected by the guaiac test and always microscopically.

However, the presence of a tumor is the chief symptom and is the first one to be noted in about 28 per cent. of the cases. The data of its detec-

tion will depend upon the site and the thoracic or abdominal development of the growth. Pain is of secondary importance; usually dull and moderate, but it may be, in some very rare cases, the only clinical symptom noted.

Analysis of the urine will usually bring forward important data, and although a Teuton has mentioned the presence of sugar in cases of malignant renal growths, he is, I believe, the only one who has been able to detect it. Histological examination of the urine may reveal the presence of neoplastic cells, but this, unfortunately, is rather infrequent.

3, RUE BELLOT.

Medicolegal Notes.

Requirement of Physical Examination Under Workmen's Compensation Act.—The provision of the Illinois Workmen's Compensation Act requiring an employee "entitled to receive disability payments" to submit, at the employer's request, to a physical examination by a duly qualified medical practitioner or surgeon selected and paid by the employer is not restricted to cases where the employer acknowledges his liability and makes compensation payments. It applies to all cases where the employee is entitled to receive disability payments as well where the employer is denying right to compensation as where he acknowledges liability and makes payment. An award will be set aside for error in not requiring the employee to submit to an examination as prescribed by the act.—*Jackson Coal Co. v. Industrial Commission*, 295 Ill. 18, 128 N. E. 813.

Physician's Right to Quit Case on Giving Proper Notice.—A physician has the right to quit a case on giving proper notice, and in a physician's action for services to the defendant's employee, where the only point of dispute was what the defendant was to pay in the event the employee got well, the defendant contending payment was only to be made out of the employee's wages, it was held reversible error to permit cross-examination of the physician as to whether he had intended to quit treating the employee before the contract with the employer was made.—*Marshall v. Brown* (Mo. App.), 224 S. W. 13.

Identification and Custody of Evidence in Prosecution for Attempt to Poison.—In case of attempt to murder by placing poison in water, objection was taken to the admission of the testimony of the chemist who analyzed the substance found in the alleged poisoned water. This chemist, who lived in Dallas, Tex., testified that he found on his desk a bottle, whose content was analyzed by him and found to be strychnine. The accused's objections were based on the lack of identification of the bottle and the failure to show proper custody of it from the time the alleged poisonous substance was placed therein until it reached the analyst. It was claimed the strychnine had been put into a water cooler at a railroad station at Avinger, Tex., with intent to kill the station agent. A witness had drank a small quantity of the water and finding it bitter threw the rest away and called the station agent's attention to the facts. An examination of the cooler disclosed a quantity of white powder floating on the ice on the top of the water, and some of this powder was sent in a bottle by Dr. J. W. Peebles to the analyst. Dr. Peebles testified that he removed some of the powder from the alleged poisoned water, placed it in a bottle, sealed it up by pasting paper across the top, and mailed it by registered letter to the chief surgeon of the railroad. This witness also identified the bottle. The analyst testified that he was told the bottle on his desk came from the office of the railroad surgeons; that it was sealed with paper, and that after analyzing its contents he gave it to the district attorney. It was held that this evidence was sufficient to take the question of the identity of the bottle and its contents to the jury. The accused was convicted, but the judgment was reversed on account of the absence of the accused's wife.—*Steele v. State*, Texas Court of Criminal Appeals, 223 S. W. 473.

RELATIONS OF PSYCHIATRY TO MEDICINE.

PSYCHIATRY is and is not a subdivision of medicine. Some old and reputable general practitioners admit that for them it is still a *terra nova* which has no connection with the requirements of a rural practice. If not to medicine then it must belong to psychology. The crux of the subject is general paralysis, for while the diagnosis of this affection was formerly wholly psychological it has now become physiopathological. Jasper has recently predicted that the psychiatry of the future would rest upon pathological brain anatomy, general somatology, legal medicine, and institution-technique; while psychology in its application to the subject matter would count only as so much dilettantism. Psychiatric psychology can go to extreme viewpoints in connection with wholesale movements like Christian science and spiritualism; for according to some writers any idea held by a sound subject is presumably sound and to prove the idea wrong we must first prove the individual himself of unsound mind. At the other extreme we have an expert opinion that a supposed dementia precox patient withstood the psychological tests successfully, but was nevertheless adjudged insane because of a positive Abderhalden reaction characteristic of this affection.

Christoffel, who discusses this subject in the *Schweizerische medizinische Wochenschrift*, February 24, 1921, li, 8, says that it was Wundt who first applied laboratory methods to psychology, which movement was extended by Kraepelin to psychopathology. Progress was the result up to a certain point and causal factors like brain lesions, intoxication, and fatigue were isolated. But technique of this sort reached its limit, and then certain theoretical anatomical lesions of minute character were postulated and a certain amount of progress resulted, mixed with much that was fanciful.

Clinical psychiatry began with Esquirol a century ago when this pioneer laid the main stress on the course of the affection in fixing its nosological position. Kraepelin has followed the same principle and has thus isolated the two major groups of dementia precox and manic-depressive insanity. Nothing definite is as yet known of the causation,

but we do know that exogenous factors play a minor rôle. Conversely, when it is the external or affective element which dominates the picture, we may influence the condition favorably by suggestive therapy. A whole school of psychiatrists have become eminent in the affective field, this culminating in psychoanalysis in which it is presupposed that the original affective element has become a part of the subconscious. Goethe with the insight of genius anticipated "conversion" and "displaced affect" in his "elective affinities." The author cites other early anticipations of Freudian teachings. Hypnosis and counter-suggestion force new affects upon the subjects and to this extent are opposite to psychoanalysis, although the discovery of psychoanalysis was founded on a hypnotic experiment intended to make the subject recall a buried affect.

Bleuler sought to show that in dementia precox the symptomatology is essentially accidental and that the real underlying condition is a splitting of the ego. He goes further and attributes to the true psychoses both psychic and physical components. Under psychotherapy these subjects may announce that they are improving and although the mental state does show improvement, the physical condition may be seen to deteriorate. Many conditions which are not regarded as psychoses show the double makeup, as hyperemesis gravidarum, enuresis, and certain painful affections. It is clear that the psychological psychiatrist should be familiar with the somatic and the medical psychiatrist with the psychologic aspect of this branch of knowledge.

INTRAUTERINE RESPIRATION IN STILLBORN CHILDREN.

It has long been taught that under certain circumstances infants *in utero* may breathe shortly before term and it is conceivable that under such circumstances they may inspire amniotic fluid and thus by interfering with the first extrauterine respirations be victims of stillbirth. On the other hand it is denied that the respiratory movements are sufficiently pronounced to permit of the inspiration of any considerable quantity of amniotic fluid, which in fact could not get below the glottis and would simply pass into the stomach. Duvoir, in an article on this subject in *La Médecine* for April 1921, ii, 7, says that Balthazard and Piedelièvre have systematically examined the histology of the lungs of stillborn children, and have often found indubitable evidence that amniotic fluid had actually entered the pulmonary alveoli. These finds are described in a thesis by Humbert (Paris, 1920) entitled "Intrauterine Submersion." The percentage of stillborn to show this evidence is placed at present at 64.

The causes appear to be varied. In the first place there should be a group in which for one or another reason the circulation in the placenta or cord has been impeded; among such cases being those due to premature detachment of the placenta and compression of the cord. Another cause during labor would be contracture of the uterus. Many obstet-

rical maneuvers may contribute to such results, as podalic version, forceps application, introduction of the balloon, any maneuvers which may stimulate the skin and provoke respiratory movements, etc. But under such circumstances labor itself has usually been dystocic and fetal death cannot imply that inspiration of amniotic fluid is the decisive causal factor. If the intake of fluid occurs during delivery the lungs should contain vaginal secretions and air from without while before labor there should only be pure amniotic fluid and meconium. The latter is seldom found, and then only when as a result of severe intrauterine asphyxia the sphincter ani of the fetus is relaxed. When this form does occur the diagnosis of submersion can be made from naked eye appearances alone.

The technique of microscopic research of the lungs for amniotic fluid has been set forth by Richter of Vienna in 1905, and is very simple. The lung tissue is squeezed out on slides and an examination is at once made without staining. The presence of amniotic fluid is recognized by the cutaneous epidermis, lanugo, etc., from the fetal skin. The other method is more exhaustive and is the one usually employed. The lungs are imbedded in paraffin and sections are made and stained. Among the finds in the alveoli have been crystals of cholesterin from the meconium. Authorities differ to some extent on the best technique for simple and differential staining. The totality of the finds of extraneous substances in the alveoli comprises horny cells from fetal epidermis, fetal down, pigment granules, and mucin. Since the bronchioles and certain areas of lung tissue may give negative results sections should be made from different parts of the lung. An insignificant amount of extraneous matter might perhaps be aspirated from the upper air passages and in the case of minimal finds care should be used in reaching an opinion. The author touches but lightly on the differentiation of antepartum and intrapartum submersion from the effects of infanticide by drowning a child which has breathed. This subject is thoroughly considered in works on jurisprudence, and what Duvoir is mainly interested in is the salvage of life possible in the case of stillbirths, for the problem looms large in connection with the low birth rate of France.

SPINAL ANALGESIA IN CHILDREN.

THE question has often been raised as to whether or not spinal anesthesia with stovaine or novocaine is feasible in children. As far back as 1905, Prelitner published a series of forty cases of spinal analgesia with cocaine in children with excellent results. Later on, Sonnenburg stated that in his opinion the use of stovaine in spinal analgesia should not be resorted to below the age of fourteen years. Columbini has affirmed that debility and old age are not contraindications for this procedure, but that it is contraindicated in children. On the other hand, Bier does not think that childhood is a contra-

indication and in the list published some time since by Barker there is a fifteen year old patient in which spinal analgesia was remarkably successful.

In 1908, Carret (Thesis, Lille, 1908) published a very interesting study of spinal analgesia from the Surgical Clinic of Lille. There were twenty-four cases in all, four in children eight years of age, three in children nine years old, seven in children of ten years, four in subjects of eleven years and six in thirteen year old children. The cases were all major operations on the lower limbs, such as amputations of the thigh or knee and arthrotomies and one case each of inguinal hernia and a cyst of the popliteal space. In a second series of sixteen cases the children were between eight and fourteen years old.

In the first series the dose of stovaine was never larger than one cgm.; in the second series the dose varied from one and a half to two cgm. of the drug, but never more. The result was that out of the total of forty cases composing the two series no phenomena of a dangerous nature were noted and only slight headache occurred. Neither was there the slightest evidence of meningeal irritation. It was found that the results were better in the second series of cases in which larger doses of stovaine were injected. Other scattered reports in literature seem on the whole to favor spinal analgesia with stovaine or novocaine in children, but it should be limited to operations on the lower limbs. It is probable that the procedure will not become a current one in infantile surgery for many obvious reasons, but it evidently has its important indications under certain circumstances. It is to be especially recommended in amputations or other serious operations susceptible of producing marked surgical shock; spinal analgesia is probably preferable, especially when the child is weak from prolonged suppuration.

The contraindications to its use are furnished by abdominal operations in which it would seem better not to resort to this procedure in young subjects. Also in very young children or very nervous ones. The simplicity of the technique, as well as the evident innocuousness of the procedure, commend it, Carret thinks, in infantile surgery in properly selected cases.

DIPSOTHYMIA AND DIPSOMANIA.

BENON, an alienist of Montpellier, has coined the word "dipsothyria" to distinguish the chronic, habitual thirst for alcohol from the peculiar intermittent craving known as dipsomania. The term "chronic alcoholism" is altogether generic and comprises several conditions. A constant thirst for alcohol is much more common than the periodical thirst, but in some dipsomaniacs the sober intervals are very short and the subjects pass readily for chronic alcoholics. Again the chronic drinker who ordinarily carries his liquor fairly well may as a result of repeated overwork or misfortune indulge excessively at short intervals and pass readily for

a dipsomaniac. In many patients the differential diagnosis is very difficult. The dipsothymic is known for making a hobby or religion out of whiskey, and under favorable circumstances would never draw a sober breath, never decline an invitation to drink and in general could be depended on to react always in the same way to the temptation of drink. But if such a man, as may happen, is often penniless or in jail, there are many intervals of enforced sobriety and when the chance comes to indulge, the subject may drink in the barbarous fashion of the born dipsomaniac. The latter, however, invariably has his lucid spells in which alcohol is specially repugnant to his senses. He may during the interval pass as a model temperance man and do uplift work. Herein, however, there is no sharp line between the man with the habitual and he with the periodic thirst. The former often wishes to break away from his curse, and after a protracted debauch during which he has lost repute and money, will make surprising efforts to rehabilitate himself. At such periods his will power is severely tested while the dipsomaniac is under no such strain—in his intervals it is no sacrifice at all to quit—in fact, it is altogether the easiest thing he can do.

The author, whose article appears in the *Gazette des Hôpitaux* for January 22, 1921, xciv, 7, gives a case history in which differentiation between the two types was extremely difficult. The subject showed a strong dipsomaniac tendency by beginning at the age of 31 to have one spree annually. He was an only son and his mother's brother was a known dipsomaniac. The rest of the history was negative. He had had these yearly sprees for 15 years and had reached the age of 46, when his attack was continued over a long period and suggested that of a chronic alcoholic addict. His spree lasted at least 9 days, but he then quickly sobered up. He later described this debauch as something unique in his experience. He did not quickly reach satiety but found new pleasures daily. He had full insight into the moral and legal hazard he ran and made attempts to break off, but the drink impulse was too strong. The attack ended only with exhaustion and profound sleep, from which he awakened not as a physical wreck with renewed cravings—which would have been the case with one who was a chronic alcoholic, but, on the contrary, with a complete loss of all desire for drink and with a deep feeling of remorse which led him to work with unusual zeal.

SIMPLE ANGINA AND ITS SEQUELÆ.

THE recently deceased pioneer of modern laryngology, Killian, delivered an address at Upsala during 1920 on the familiar but little understood condition, angina simplex, based on twenty years of continuous special study. A digest of the original report is found in the abstract columns of the *Schweizerische medizinische Wochenschrift* for May 12, 1921, li, 19. According to the author, the disease usually begins in the vault of the

pharynx. On the first day the subject complains of high fever, headache, fatigue, and anorexia. Posterior rhinoscopy as a rule shows swelling and redness of the pharyngeal tonsil, and at times there is a membranous deposit. Later and, as a rule, by the second day of the fever, there is noted the supervention of redness of the faucial tonsil, with the characteristic white points, seen especially on the latter and the lingual tonsil. In a minority of cases the condition is limited to the pharyngeal tonsil. If the practitioner does not use the pharyngeal mirror the enlarged submaxillary lymphnodes will locate the process. The most important complication in simple angina is prolongation of the fever for from one to three weeks. Killian was able to abort this fever by expressing the plugs from the tonsillar crypts. This is the best proof that tonsillar plugs may cause toxic and septic conditions. One should not try to express these plugs during the first few days of the angina, for during this period they are too adherent to the tonsil, as the result of the outpouring of tenacious fibrin. Aside from continued fever there are many complications of angina simplex. Most of these come under the head of tonsillar focal infection. Peritonsillar abscess and phlegmon occasionally supervene as sequelæ. In a certain number of cases acute tonsillar infection passes to the chronic stage with a second series of focal infections, tonsillar abscesses, etc. In the treatment of the chronic as well as of the acute cases, the aim is disinfection of the diseased tonsils.

HEMOCLASTIC CONSEQUENCES OF BOLTING FOOD.

THE late Horace Fletcher, who preached the gospel of slow mastication and attributed many of the ills of mankind to the reprehensible practice of bolting one's food, would have been greatly pleased by an observation recently reported by Pagniez and de Gennes (*La Presse Médicale*, April 27, 1921, xxix, 34) of a man who, whenever he ate rapidly, developed an urticarial outbreak. This phenomenon seems to have been of daily occurrence, although it had begun only a few months before the man was seen by the authors. He had made various changes in his diet but none in his manner of eating. He ate with extreme rapidity but bolting his food had caused him no digestive disturbances. As soon as he had acquired the habit of eating slowly the rash ceased to appear. After three weeks' immunity the authors asked the subject to resume his old habit of bolting in order that blood tests might be made. Nothing happened until the fourth day, when hives broke out with itching. The man was subjected to experiment for several months and the possibility that the eruption was due to any particular kind of food was eliminated. A complete hemoclastic crisis did not occur but leucocytosis was affected in that the phenomenon of digestive leucocytosis did not appear as usual. This absence had been noted by the authors before in certain cases of urticaria and migraine in which an anaphylactic origin had been demonstrated. It is evident that the mechanism of the phenomenon in the case reported was complex and could not be regarded as a simple reflex.

AN APOLOGY TO DR. MORTON PRINCE.

THE publishers of Dr. Morton Prince's work entitled "The Unconscious" have called our attention to the almost literal, and indeed for the most part exact, correspondence between a section on pages 391-410 of that work, published in 1914, and an article entitled, "Technique of Psychoanalysis as Practised in a Case of Phobia", alleged to have been written by Dr. H. Laveson of this city and published in the MEDICAL RECORD of May 21, 1921. Comparison of the article and the section noted in the book confirms this assertion. We apologize to Dr. Morton Prince and to the Macmillan Company, publishers of the book, for this rank plagiarism by one of our contributors, and we assure them that Dr. Laveson will never have an opportunity to repeat this performance in the columns of the MEDICAL RECORD.

News of the Week.

Smallpox Outbreak in Arkansas.—Thirty-two cases of smallpox have been reported among the 1800 residents of Pocahontas. An investigation of the epidemic by the State Board of Health of Arkansas shows that the outbreak originated with an unvaccinated seventeen-year-old girl in the public school.

New Decision Upholds Law Governing Vaccination.—A writ of mandamus brought by a parent to compel the Haverhill (Mass.) school board to allow his three children to attend the public schools without complying with the regulation of the school committee, providing that every pupil who has been given a certificate by a physician, stating that such pupil is not a fit subject for vaccination shall be required to renew such certificate once in two months, has been dismissed by the court. The decision declares that the intent of the Legislature clearly is that exemption from vaccination is not to cover the entire period of a child's attendance and that such certificates are limited to the period when the child's physical condition is such as, in the opinion of a physician, to unfit him for vaccination at that time.

Public Health Committee of the New York Academy of Medicine.—At the meeting of this committee on June 6, the question of the proposed abolition of the Division of Industrial Hygiene of the Health Department of the city was discussed. The committee voted to support the position taken by the Commissioner of Health in urging the retention of this bureau. The work done by this bureau could not be fully carried out by the State Department of Labor because of lack of sufficient personnel. Moreover, so far as the city was concerned it would really not secure any important saving of expenses. This protest was sent to the members of the Board of Estimate and Apportionment.

The Committee also discussed the Shepard-Towner Bill, now before Congress, which aims, in addition to administrative expenses, to appropriate a certain sum of money to the different States of the Union, provided they will also furnish an equal sum for the purpose of cooperating in promoting the care of maternity and infancy. The matter had been referred to a subcommittee and the purposes as well as the principle underlying the bill were very

carefully considered. The subcommittee reported that it would be undesirable to take any action on this bill at the present time because the questions of health and welfare were undergoing a reorganization.

House of Delegates of the American Medical Association Sidesteps the Alcohol Question.—At the recent meeting of the American Medical Association a resolution, introduced before the House of Delegates by Dr. Victor C. Vaughan of Ann Arbor, Mich., to the effect that the Association reiterated and reaffirmed its judgment of 1917 that the use of alcohol as a beverage was detrimental to human economy and that there was no scientific basis for its use as a food and in the treatment of patients, gave rise to a three hours' debate behind closed doors. The resolutions were finally referred to the Committee on Scientific Research with instructions that it give the subject full investigation and submit a report at the next meeting.

Protests Against the Volstead Act.—At the annual meeting of the American Medical Editors' Association in Boston last week resolutions were adopted declaring that the medical restrictions of the Volstead Act, together with its various administrative and other interpretations are obstacles to the free practice of therapeutics, and have reacted to the detriment of society and the public health; that the American Medical Editors' Association protests against further undue regulation of therapeutic procedure by statute or by administrative interpretation or regulation; and that the Association requests of the proper authorities a review and revision of such existing statutes, rules, and regulations as may be unduly restrictive of the therapeutic judgment and procedure of physicians.

The Right to Prescribe.—At a recent meeting of the Lycoming County (Penn.) Medical Society resolutions protesting against the interference of the government with the power of physicians to prescribe for their patients were adopted. These resolutions were presented before the House of Delegates of the American Medical Association.

Fordham Medical College to Close.—Announcement was made a few days ago that the medical school of Fordham University in New York would cease to exist with the close of the graduation exercises on Thursday of this week. The school has been in existence for sixteen years and was in the A class of medical colleges. During the war it sent over an ambulance and a hospital unit recruited from graduates and undergraduates of the school. Want of funds is the cause of the discontinuance of classes, the annual deficit amounting to over \$20,000 a year.

Medical College Commencements.—At the commencement exercises of New York University, 111 of the 966 degrees conferred were bestowed upon medical students. At the same time Chancellor Elmer Ellsworth Brown announced an expansion of the medical department. A seven-story structure is to be added to the medical group, the primary purpose of which will be to provide satisfactory housing for the New York State Bacteriological Laboratory. Two floors will be devoted to a laboratory and museum for the teaching of preventive medicine, hygiene and sanitation, the Rockefeller Foundation having contributed \$35,000 for this purpose.

The Jefferson Medical College of Philadelphia, at its commencement exercises on June 4, conferred the degree of Doctor of Medicine on 114 graduates.

Forty graduates of the New York Homeopathic Medical College and Flower Hospital received their diplomas at the sixty-first annual commencement of this institution, which was held in the Hotel Astor on June 9. Dr. Samuel B. Moore, president of the Medical Board of the Metropolitan Hospital, administered the Hippocratic oath.

China Will Adopt U. S. Pharmacopœia.—The United States Pharmacopœia is being translated into the Chinese language under the auspices of the Philadelphia College of Pharmacy and Science. Germany before the war is said to have tried every means to have the German Pharmacopœia translated into Chinese in order that German manufacturers might export to China drugs of German standards, and it is understood that Great Britain has made a similar effort since the war. Through the adoption of American standard formulas for drugs and medicines, it is expected that American drug manufacturers will be greatly benefited.

New York Celebrates "Milk Week."—During the week beginning June 6, the New York Health Department conducted a campaign to increase the use of milk as a food not only for babies but for adults as well. Bars where milk was served were conducted in all drug stores throughout the city. One of the features of the campaign was a drive to secure funds to provide pure milk for babies during the summer.

St. Louis Hospital Acquires New Site.—The Liberty Hospital, located at Delmar Boulevard and Pendleton Avenue, has purchased a lot 100 x 200 feet at the southwest corner of Washington Boulevard and Taylor Avenue, where it plans to erect a hospital building at a cost of \$500,000.

Fake Arsphenamine.—A preparation purporting to be arsphenamine of German origin has been sold in New York City by seamen and other unscrupulous vendors. Upon investigating these sales and making analyses of the substance the New York Health Department has found it to be a substitute for asphenamine, composed of sodium chloride and a yellow dye. The New York City Health Department warns physicians and druggists against purchasing such products from unknown persons.

Hospitals Get Whiskey.—United States Judge Thomas I. Chatfield in Brooklyn recently sustained the decision of Federal Judge Garvin, ordering the release for distribution to hospitals of 1076 gallons of bonded whiskey which were seized in the Long Island Railroad yards in Long Island City last December.

The Alaskan Territorial Medical Society, at the recent meeting of the American Medical Association, was admitted as a constituent member of the association.

The Second English-Speaking Conference on Infant Welfare will be held at the Central Hall, Westminster, London (instead of at the Kingsway Hall, as previously announced), on Tuesday, July 5, Wednesday, July 6, and Thursday July 7, 1921, from 10 to 1 and from 2:30 to 4:30 each day. The Child Welfare Exhibition will be open from Tuesday, July 5, to Saturday, July 9, from 11 A. M. to 9 P. M., in the Central Hall, Westminster, ground

floor. It will include the latest exhibits and posters relating to the welfare of mothers and babies, including a special section arranged by the Child Hygiene Association of the United States. Demonstrations from 11 A.M. to 9 P.M., on the care of the baby, including feeding, cookery, toilet, exercise, clothing, sleep, habits, etc. Illustrations of the work in Day Nurseries, Nursery Schools, and Montessori Schools, also of the teaching of infant care to schoolgirls. Child Welfare doctors, dentists, and oculists will be in attendance daily to give free consultations and advice on the health of mothers and young children. Throughout the week a large number of Infant Welfare Centers, resident institutions of all kinds for mothers and babies, day nurseries, nursery schools, etc., will be open for inspection by delegates to the conference. The conference fee, including admission to the exhibition and to the evening lectures, the right to receive proofs of the papers to be read, and a copy of the report of the proceedings when published, has been fixed at £1 1s. per member. Tickets are to be obtained from Miss Halford, Secretary, National Association for the Prevention of Infant Mortality, 4 and 5, Tavistock Square, London, W. C. 1.

Charitable Gifts and Bequests.—The Carnegie Corporation announces an appropriation of \$100,000 for the use of the National Board of Medical Examiners in a period of five years.

By the will of the late Pemberton Hollingsworth of Philadelphia, the sum of \$5,000 is bequeathed to the Presbyterian Hospital in honor of Dr. H. R. Wharton, and the sum of \$10,000 each to the Chestnut Hill Hospital, for a room in memory of Laura Albert Hollingsworth, and to the Presbyterian Hospital for a room in memory of his mother, Anna Clifford Hollingsworth.

The General Education Board of the Rockefeller Foundation has made a gift of \$3,000,000 to the trustees of Vanderbilt University to be used in the development of the School of Medicine.

At the commencement exercises of New York University, Chancellor Elmer Ellsworth Brown announced the following gifts: For university endowment, \$200,000 from the Carnegie Corporation; for additions to the Edward Gibbs Memorial X-Ray Laboratory, an addition of \$1,000 to a former benefaction by Mrs. Charles H. Sherrill; a gift of \$150,000 from Mrs. Helen Hartley Jenkins to complete an endowment of the department of medicine for which Mrs. Jenkins had previously contributed \$100,000. This endowment is a memorial to Alexander A. Smith.

The will of the late Daniel Fraser of Washington, D. C., provides for the following bequests: the Garfield Memorial and Homeopathic Hospitals, Washington, each \$25,000; the Northern Infirmary, Inverness, Scotland, \$15,000; the Inverness Home for Convalescents, \$10,000.

The Children's Homeopathic Hospital and the Lankenau Hospital, Philadelphia, receive bequests of \$5,000 each under the will of the late Alfred E. Bruk of Philadelphia.

The Rochester Homeopathic Hospital, at Rochester, N. Y., is a beneficiary of the will of Bertha E. Hoxie to the extent of \$6,000, to be used for the endowment of a permanent bed.

Dr. T. Mitchell Prudden of New York has been elected a member of the International Health Board of the Rockefeller Foundation.

Dr. Brandreth Symonds of New York received the honorary degree of Doctor of Laws at the ninety-sixth Commencement of Hobart College on June 13, in recognition of his services to the cause of public health.

Dr. George David Stewart of New York received the degree of Doctor of Laws from the New York University at its commencement exercises on June 8.

Dr. John A. Kolmer, Professor of Bacteriology in the Graduate School of the University of Pennsylvania received the degree of Doctor of Science at the commencement of Villanova College on June 9.

Dr. Simon Flexner delivered the commencement address at Bryn Mawr College on June 9. He urged women, now that opportunity had opened the door, to take up the pursuit of science for which he believed they possessed particular aptitude.

Professor José María Albanana Sanz of Madrid has been sent to Mexico by royal order to investigate the primitive medicines of the Aztecs and their influence over modern European medicines. He will leave Spain this month.

Dr. Harold E. Anderson has been appointed surgeon-dentist to St. Mary's Hospital, Hoboken.

Licensing of Mechanotherapeutists.—A bill now before the Illinois Legislature to license practitioners of mechanotherapy is strongly opposed by the medical practitioners of the State. In the bill mechanotherapy is defined as "the relieving and treatment of human ailments by mechanical means, especially by massage and gymnastic exercise." The medical men believe that were this bill to become a law men licensed thereunder could rightfully contend that treating fractures with splints and plaster of paris casts and even surgical operations with the use of instruments could be defined as coming under the provisions of this measure. Objection is also raised to another section of the bill which reads: "No person who has received a license to practise mechanotherapy in this State shall make a diagnosis of human ailments or prescribe or administer drugs, except under the direction of a duly licensed physician." This would give the mechanotherapist the right to prescribe or administer drugs under the direction of a licensed physician, but it is not clear just what the term "direction" of a physician means. It could be construed in many objectionable ways.

Medical Society Elections.—THE MEDICAL ASSOCIATION OF GEORGIA, at its seventy-second annual meeting held in Rome, May 10-12, 1921, elected the following officers: *President*, Dr. E. G. Thrash, Atlanta; *First Vice-President*, Dr. H. W. Terrell, LaGrange; *Second Vice-President*, Dr. R. M. Harbin, Rome; *Secretary-Treasurer*, Dr. A. H. Bunce, Atlanta.

THE WEST TENNESSEE MEDICAL SOCIETY, at its annual meeting held in Paris, May 13, 1921, elected the following officers for the ensuing year: *President*, Dr. C. H. Johnston, Lexington; *Vice-Presidents*, Dr. R. L. Motley, Dyersburg, and Dr. T. B. Wingo, Martin; *Secretary-Treasurer*, Dr. Isaac A. McSwain, Paris; *Assistant Secretary-Treasurer*, Dr. George R. McSwain, Paris.

THE CALIFORNIA STATE MEDICAL SOCIETY, at its annual meeting held in San Diego, May 11-13, 1921, elected the following officers for the ensuing year: *President*, Dr. H. G. Brainerd, Los Angeles; *First Vice-President*, Dr. Alfred C. Reed, San Francisco; *Second Vice-President*, Dr. Joseph H. Catton, San Francisco; *Secretary*, Dr. W. E. Musgrave, San Francisco.

THE FLORIDA MEDICAL ASSOCIATION, at its meeting held in Pensacola, May 12, 1921, elected the following officers for the ensuing year: *President*, Dr. S. R. Mallory Kennedy, Pensacola; *First Vice-President*, Dr. L. M. Anderson, Lake City; *Second Vice-President*, Dr. Wellcome Herbert Adams, Jacksonville; *Third Vice-President*, Dr. J. C. Davis, Jr., Quincy; *Secretary-Editor*, Dr. Graham E. Henson, Jacksonville.

THE MISSISSIPPI MEDICAL ASSOCIATION, at its annual meeting held in Laurel, May 11, elected the following officers for the ensuing year: *President*, Dr. Henry Boswell, Sanitorium; *First Vice-President*, Dr. J. A. Mason, Cold Water; *Second Vice-President*, Roland H. Cranford; *Secretary*, Dr. T. D. Dye, Clarksdale; *Treasurer*, Dr. J. M. Buchanan, Meridian.

THE NEBRASKA STATE MEDICAL ASSOCIATION, at its annual meeting held in Lincoln, May 12, 1921, elected the following officers for the ensuing year: *President*, Dr. B. B. Davis, Omaha; *First Vice-President*, Dr. Porter F. Dodson, Wilber; *Second Vice-President*, Dr. P. R. Howard, North Bend; *Secretary-Treasurer* (short term), Dr. E. R. Manning, Omaha; *Secretary-Treasurer* (long term), Dr. R. B. Adams, Lincoln.

THE LOGAN COUNTY (ILL.) MEDICAL SOCIETY, at its annual meeting held in Lincoln, May 13, 1921, elected the following officers for the ensuing year: *President*, Dr. C. B. Caldwell, Lincoln; *First Vice-President*, Dr. Forrest Van Hook, Mt. Pulaski; *Second Vice-President*, Dr. J. H. Butler, Lincoln; *Secretary-Treasurer*, Dr. E. C. Gaffney, Lincoln.

THE ELEVENTH CONGRESSIONAL DISTRICT MEDICAL SOCIETY OF INDIANA, at its semi-annual meeting held in Logansport, May 19, 1921, elected the following officers for the ensuing year: *President*, Dr. Ira Perry, North Manchester; *Secretary-Treasurer*, Dr. J. H. Reed, Logansport.

THE IOWA STATE MEDICAL SOCIETY, at its seventieth annual meeting held in Des Moines, May 12-14, 1921, elected the following officers for the ensuing year: *President*, Dr. Alanson M. Pond, Dubuque; *First Vice-President*, Dr. S. A. Spilman, Ottumwa; *Second Vice-President*, Dr. M. A. Tinley, Council Bluffs; *Secretary*, Dr. T. B. Throckmorton, Des Moines; *Treasurer*, Dr. T. F. Duhigg, Des Moines.

THE ARKANSAS ECLECTIC MEDICAL ASSOCIATION, at its meeting held in Little Rock, May 14-16, 1921, elected the following officers for the ensuing year: *President*, Dr. J. F. Hilburn, Pine Bluff; *First Vice-President*, Dr. R. C. Norris, Tuckerman; *Second Vice-President*, Dr. B. D. Clutch, Booneville; *Secretary*, Dr. S. G. Boyce, Little Rock; *Treasurer*, Dr. C. E. Spann, Altheimer.

THE HOMEOPATHIC MEDICAL SOCIETY OF WISCONSIN, at its annual meeting held in Milwaukee, May 12-14, 1921, elected the following officers for the ensuing year: *President*, Dr. F. T. Clark, Waupun;

Vice-President, Dr. J. M. March, Elkhorn; *Secretary*, Dr. John F. Guy, Milwaukee; *Treasurer*, Dr. F. E. Brown, Milwaukee.

THE INDIANA INSTITUTE OF HOMEOPATHY, at its annual meeting held in Indianapolis, May 12, 1921, elected the following officers for the ensuing year: *President*, Dr. C. A. Walton, Anderson; *Vice-Presidents*, Dr. G. A. Low, Indianapolis; Dr. E. R. Wallace, Aurora; *Secretary*, Dr. J. D. Coons, Lebanon; *Treasurer*, Dr. J. C. Slaubaugh, Nappanee.

THE MEDICAL SOCIETY OF NORTH VIRGINIA AND THE DISTRICT OF COLUMBIA, at its meeting held in Alexandria, Va., May 18, 1921, elected the following officers for the ensuing year: *President*, Dr. Stephen Hamsberg, Catletts, Va.; *First Vice-President*, Dr. W. L. Lewis, Kensington, Va.; *Second Vice-President*, Dr. V. P. Borden, Washington; *Recording Secretary*, Dr. William T. Davis, Washington; *Corresponding Secretary*, Dr. Joseph J. Rogers, Washington; *Treasurer*, Dr. Robert S. Lamb, Washington.

THE ESSEX SOUTH DISTRICT (MASS.) MEDICAL SOCIETY, at its annual meeting held in Lynnfield, Mass., May 12, 1921, the following officers were elected for the ensuing year: *President*, Dr. P. P. Johnson, Beverly; *Vice-President*, Dr. J. B. MacDonald, Hathorne; *Secretary*, Dr. G. E. Tucker, Salem; *Treasurer*, Dr. G. Z. Goodell, Salem.

THE FRANKLIN DISTRICT (MASS.) MEDICAL SOCIETY, at its annual meeting held in Greenfield, May 13, 1921, elected the following officers for the ensuing year: *President*, Dr. J. H. Mather, Greenfield; *Vice-President*, Dr. J. A. Suitor, South Deerfield; *Councilors*, Dr. H. G. Stetson, Dr. H. N. Howe, and Dr. Charles Moline, Sunderland; Dr. Roscoe Philbrick and Dr. A. L. Newton, Northfield.

THE BAYONNE (N. J.) MEDICAL SOCIETY, at its annual dinner meeting held May 19, 1921, elected the following officers for the ensuing year: *President*, Dr. A. J. Malloy; *Vice-President*, Dr. E. E. Lupin; *Secretary*, Dr. W. L. Williamson; *Reporter*, Dr. E. S. Klugman.

Obituary Notes.—Dr. L. A. SPAULDING, a graduate of the Medical College of Ohio in 1878, died at his home in Bluffington, Ind., on May 13, at the age of seventy-three years.

Dr. FRANK BORSODY of New York, a graduate of the Royal Hungarian University, Budapest, in 1872, died May 19, at the age of seventy-five years.

Dr. FRANK PIERCE KENYON of Pomona, Cal., died following a surgical operation in a local hospital on May 8, at the age of sixty-seven years.

Dr. EDGAR DINKELSPIEL of New York, a graduate of the University of California in 1899, died at his residence on May 23, at the age of forty-four years.

Dr. ABRAHAM MANDELBAUM of Brooklyn, a graduate of the Maryland Medical College, Baltimore, in 1900, died in a local hospital on May 24, at the age of fifty years.

Dr. GUY CARLETON BAYLEY of Poughkeepsie, N. Y., a graduate of the College of Physicians and Surgeons, New York, in 1872, died on May 24, at the age of seventy years. He was surgeon in chief of the Vassar Brothers' Hospital from its founding until 1907.

Dr. THOMAS HARVEY WILLIAMS of Neshoba, Tenn., a graduate of Jefferson Medical College in 1872, died May 18, at the age of seventy-one years.

Dr. CHARLES F. MCCARTHY of Winchester, Conn., a graduate of Long Island College Hospital in 1890, died after a lingering illness on May 19, at the age of fifty-one years.

Dr. WARREN HUGH MAUZEY of Findlay, Ill., died on May 17 at the age of fifty-five years. He was graduated from the Louisville Medical College in 1898.

Dr. CHARLES D. BRINER, a graduate of Starling Medical College, Columbus, in 1886, died of Bright's disease at his home in Williamsport, Ohio, on May 20, at the age of fifty-eight years.

Dr. SIMON B. RICHMOND, physician to the Boys' Industrial School, Pine Bluff, Ark., died there on May 12, at the age of sixty years.

Dr. GEORGE W. MILLER, a graduate of the Miami Medical College, Cincinnati, in 1901, died at his home in East Chicago, Ind., May 12, at the age of forty-four years.

Dr. RIVES ANDREW MANKER of Memphis, Tenn., a graduate of the Memphis Hospital Medical College in 1908, died from heart trouble in a local hospital on May 19, at the age of thirty-eight years.

Dr. IRVING J. WOODIN of Independence, Cal., died from cancer in Los Angeles on May 10, at the age of sixty-nine years. He was graduated from the Long Island College Hospital in 1874.

Dr. HARRY M. SHERMAN of San Francisco, Professor of Surgery in the University of California, died following an attack of bronchial trouble on May 15, at the age of sixty-seven years. He was a graduate of the College of Physicians and Surgeons, New York, in 1880, and a Fellow of the American College of Surgeons. He was director of St. Luke's Hospital.

Dr. ROBERT W. MCCLELLAND of Pittsburgh, Pa., died in the Hahnemann Hospital on May 18. He was graduated from the Hahnemann Medical College and Hospital, Philadelphia, in 1884. He was a member of the American Institute of Homeopathy.

Dr. J. B. FINCH of Dresden, Tenn., a graduate of Vanderbilt University Medical Department, Nashville, Tenn., in 1880, died suddenly May 20, at the age of sixty-four years.

Dr. HENRY J. CUMMINGS, a graduate of Trinity Medical College, Toronto, in 1889, died at his home in St. Louis, May 15, following two months' illness, at the age of fifty-four years.

Dr. CLINTON STUART KERR of Los Angeles, Cal., and Emlenton, Pa., died in the latter place on May 20. He was graduated from the Cincinnati College of Medicine and Surgery in 1876.

Dr. JOHN WILSON, for sixty years a practitioner of medicine, died at his home in Tacoma, Wash., on May 14, at the age of ninety-one years.

Dr. MELAMED OVIDIN, a graduate of the Temple University Medical Department, Philadelphia, Pa., in 1909, was shot and killed by an insane patient at the National Soldiers' Home in Togus, Me., on May 25. He was forty-three years of age.

Dr. HARLOW A. WHITNEY of Northfield, Mass., a graduate of the University of Vermont College of Medicine in 1907, died after a lingering illness on May 20.

Dr. RICHARD WILLIAMS WOOTEN of Kinston, N. C., a graduate of the University of Virginia Medical Department in 1870, died on May 17, at the age of seventy-two years.

Correspondence.

THE CASE OF CUSACK VS. MORRIS

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—On the way to the meeting of the American Medical Association with a group of doctors bound for Boston, I find a general expression of regret that the details of the suit against me have not become available, as the case was discontinued. A number of important points were involved.

Some years ago I presented at a meeting of the Surgical Society in New York a man who had lost both testicles in youth as a result of mumps. There was no sex power or feeling. A small graft had the peculiar effect of stimulating the remains of one testicle into development, although the graft itself was absorbed. The patient gained sex power and married.

Three years ago a patient, Mr. H., came to the Post Graduate hospital for removal of a small tumor of the leg. He had undeveloped testicles although he was a man in good health and since that time has been married. It occurred to me, having the former case in mind that a graft of testicle tissue might stimulate the development of the testicles with the effect of perhaps lowering his voice at least, through enzymic response. I told him that if he would come to the hospital on some occasion when I had trimmings from a hydrocele operation I might try these for endocrine effects. Some time later a patient, Mr. Cusack, was sent to me by his family physician for an operation for double inguinal hernia and hydrocele of the right side.

Many years ago at the Ithaca Hospital after a Bergmann operation for hydrocele there was a return of the condition a year or so later. At the first operation I had removed only the parietal layer of the sac. At the second operation to insure a radical cure I removed the visceral layer, marked off lines with a scalpel and then with curved scissors removed peritoneum and found that no harm was done if some of the tunica albuginea and adherent tubules were included here and there among the trimmings. Since that time I have regularly done this addition to the Bergmann operation.

Knowing that we were to have trimmings of this sort I asked Mr. H. to allow me to use some of the material, small pieces of which, including several kinds of structure, were inserted in the abdominal wall beneath the sheath of the rectus muscles. Incidentally it may be remarked that in this case the tissue was absorbed after the operation. In the case of Mr. C. the hernial and hydrocele wounds had become healed to such a degree at the end of a fortnight that I informed him he might return home on the following day. Incidentally there had been a collection of brownish fluid at the hydrocele site, which I took to be ordinary serous oozing, at the time when it was withdrawn with the needle. I then left town for a Medical Society meeting at a distance. In my absence it was found that an infection was under way at the hydrocele site with the formation of an abscess. Because of the late development of this complication it was presumed to be a catgut infection.

My colleague on the staff, Dr. S., who had a pa-

tient in the next room, was called in to help out with my patient in my absence. He opened the abscess and incidentally asked another colleague, Dr. E., to be present at the operation. Dr. S., Dr. E., and I had previously had a good deal of controversy over the employment of rubber gloves in surgery. In this particular case I had worn gloves, as they are discarded in my abdominal work only, for reasons stated in various published contributions on the subject. The result of the abscess on the right side was a defect in contour which may be remedied. There is no loss of virility.

The patient gained the impression that I was responsible for his trouble and through Mr. Leo Levy brought suit for felonious assault and \$250,000 damages. Mr. Levy began proceedings in a way which displeased my counsel, Mr. James Taylor Lewis, then counsel for the New York State Medical Society. Because of this legal hitch the case passed into the hands of Mr. Cornelius J. Smyth. Mr. Smyth, examining into the various features, found it desirable to call Mr. George Gordon Battle to his aid.

Mr. Battle having examined me in advance of trial in the presence of the plaintiff and others interested, decided that it was a case which he did not care to try. Mr. Smyth next called in Mr. W. J. Fallon. The case has now been discontinued on the request of Mr. Cusack, who learned the real facts for the first time when Mr. Battle made the preliminary examination before trial.

It is necessary to correct several points of misconception which have been widespread and of which I have heard not only from various parts of this country but from abroad. It was said that Mr. H. paid me a large fee for the grafting operation. Mr. H. paid me nothing at all for this, as it was simply a bit of side experiment made at a time when I hoped to be of service both to Mr. C. and to Mr. H.

It has been said that I paid a large sum of money for discontinuance of the suit. I have paid nothing at all for this. On the other hand, my counsel, Mr. Lewis, will be witness to the fact that I have urged him during these three years to bring the case to trial at the earliest possible moment. My witnesses in the case were members of the Surgical Society, doctors who assisted me previously and at the time when I did this particular form of hydrocele operation and doctors who had adopted the same form of operation themselves. The witnesses against me were two doctors whom I did not know personally. They were paid \$150.00 each for examining the patient and they are said to have received their information about the case from a doctor who was not present at the operation. There was no question in my mind of bad faith on the part of these two doctors who were to have been witnesses against me.

Legal points in the case relate to the employment of waste materials without the consent of the party from whom they were removed. Skin, bone, and other tissues are so frequently used in this way that it was believed that the point would not require adjudication.

ROBERT T. MORRIS, M.D.

616 MADISON AVENUE,
NEW YORK.

OUR LONDON LETTER.

(From Our Own Correspondent.)

LONDON, May 17, 1921.

The Queen and Medical Women.—In a letter sent a short time ago a brief account was given of the new unit of obstetrics and gynecology, established at the Royal Free Hospital, London, the Women's Medical School. It was mentioned that this unit was the first recognized by London University, of obstetrics and gynecology in London. Attention may be further drawn to the fact that the Royal Free has always been a pioneer among the London hospitals. In 1828 it was the first to admit indigent men, women, and children without any of the formalities which had to be gone through before admittance was granted to the other hospitals. Again in 1877 it was the first to make the new departure of admitting female students to its wards, in 1896 it made another forward step by appointing woman graduates as medical and surgical registrars, and in succeeding periods it opened its resident posts to women graduates and elected two women graduates to its honorary staff. Strictly speaking the London School of Medicine for Women is situated in Hunter Street, W. C., in convenient proximity to the Royal Free Hospital, but all the clinical work is done at the Royal Free Hospital. This hospital is the only one in London which is absolutely open to female medical students. Some of the other big hospitals admit quite a limited number of these and the remaining ones refuse to admit them. This being the case girl students in great numbers flock to the London School for Women and its subsidiary hospital with the consequence that the clinical facilities have had to be extended. Accordingly in 1915 a fund was opened to extend the hospital on land presented by its chairman. A total of £500,000 is required to carry out the full scheme, but already the unit of obstetrics and gynecology has been created and 100 additional beds equipped for that neglected and large class of patients who are unable to obtain free treatment, who have no proper facilities for operations in their own homes and cannot afford to pay the high fees of a good nursing home.

The Queen, on May 11 last, opened the new clinical unit of obstetrics and gynecology of the Royal Free Hospital. Miss Aldrich Blake, M.D., the dean of the Medical School, welcomed the Queen on behalf of the school and hospital and of past and present students, and said in part, that clinical units in medicine and surgery had recently been created in some of the other medical schools in London, but they had the honor, they hoped not inappropriately, to be the first to have a unit in obstetrics and gynecology. For this new development in the teaching of clinical subjects the medical schools were indebted to the Board of Education and the University Grants Committee. For the conditions which had made the unit possible there they had many friends to thank. They owed thanks to Lady Barrett, now consulting obstetrician to the hospital, for the energy and initiative which developed the department of midwifery; to the Duchess of Marlborough both for her own great gifts and for £10,000 which came to them by her influence with the American Red

Cross; and they wished to thank the American Women's Club for the equipment of wards and their constant helpful interest in the patients in them. During the tour of the hospital Dr. May Thorne addressed the company and said that all present felt that the Queen was there because she was keenly interested in the medical education of women, and therefore interested in the Royal Free Hospital, as that hospital had been the alma mater of the medical education of women in England for well over forty years. The jubilee of the hospital would occur in 1924 and by that time they would like to have the extension of the hospital built and equipped and containing sufficient beds to enable them to have units of medicine and surgery in addition to the unit which had been opened that day.

Hospital Crisis.—According to the *Pall Mall* and *Globe*, May 17, 1921, it would really seem that our great hospitals are at last awakening to realities and are recognizing that only by frank acceptance of the paying patients is State control to be avoided. Everyone who knows anything of State control also knows that under its blighting influence the hospital as we have come to know it would disappear. It is regrettable that the hospital managements have been so slow to recognize the social changes of the time, changes that have cut off the old flow of subscriptions and created a new poor that cannot pay the fees of fashionable surgeons and nursing homes. It is regrettable because had the paying system been introduced earlier we should not have had such statements as those recently issued by great hospitals to the effect that they are closing down wards owing to lack of funds to carry on. King's College Hospital, which is one of those in distress, has said that when the occupied beds are reduced to 200, a paying system will be introduced. It is to be hoped that when it is introduced it will be planned upon a businesslike basis, for it appears certain that if the public need is properly catered for by a graduated system of payment for value received, no more will be heard of insolvency, although really necessitous uninsured patients are accepted without charge. On the whole the above seems to be a reasonable statement, and it is probable that the introduction of a system of paying patients on a graduated scale would nominally save the situation or, at any rate, effect a great amelioration. At the present time while the hospitals are free to all, as a matter of fact they are closed to the very people who need their services most. The middle class are really the poor now. They cannot get into the big hospitals and are unable to pay the charges of the nursing homes. It is only the rich and the presumably poor, the working classes, who receive skillful and adequate medical and surgical treatment when they are truly ill. But over and above, the introduction of the pay system, better management or rather organization of the hospital system is called for if these institutions for the sick are to be placed on a sound financial basis. The voluntary system is not actually defunct, it only requires to be wisely modified and revised.

Spahlinger Serum for Tuberculosis.—One or two of the lay papers here, and especially one of

the Sunday papers, continue to extol the Spahlinger treatment for tuberculosis and almost to revile the Government, represented by the Department of Health, for not taking a more active interest in the matter. As mentioned in a former letter many questions on the subject have been asked in the House of Commons and a really extraordinary concern has been manifested by all sorts and conditions of men. This curiosity on the part of the general public is not to be wondered at for it has been unduly fanned by certain journals. While the lay press has given much prominence to the serum, the British medical press has observed a discreet reticence, and as said before the Ministry of Health does not appear to think it worth while to make any special investigations. The most recent communication was made by Spahlinger through Professor D'Arsonval to the Académie des Sciences and this report included the treatment of cases by two British physicians, Dr. Croucher and Dr. Leonard Williams. The former gave a very favorable report of the cases treated by him by this method. Dr. Williams described several cases of surgical tuberculosis and of open pulmonary tuberculosis with bacilli in the sputum, which he declared are now free from active disease. Lastly, Dr. W. Camac Wilkinson, in the *British Medical Journal* of February 26, stated that he had studied the evidence in favor of M. Spahlinger's treatment and discussed his point of view with him at an interview. Dr. Wilkinson said that it was practically the same method that he had been using for the past thirty years and, of course, he is strongly in favor of it. The details given of the treatment are meager and vague in the extreme. Professor D'Arsonval merely states that "acute cases are treated by means of complex antitoxic and bacteriolytic serums, and that chronic cases are dealt with by vaccination with a series of antigens and ferments, the former of these being derived from the bacillary substance of the tubercle bacillus. The Swiss correspondent of the *Lancet* is sceptical of the whole matter. It may be pointed out that more than one serum has been produced for the treatment of tuberculosis, all of which have been lauded as cures, and it may be added that none has met with success. The composition or method of preparation of these serums was made known in every instance, but so far as Spahlinger's serum is concerned absolutely no information has been forthcoming. Consequently it is impossible to pass an opinion and the secrecy observed does not tend to inspire confidence in its curative merits. People on your side of the water probably still remember the furore, not to say uproar, with which the Friedman turtle serum was greeted a few years ago, and the laudation it received from yellow journals and even some medical men who ought to have known better.

The Danger of Athletics for Women.—Since a meeting was held a short time ago to protest against the cult of athletics for girls and women, or at any rate, to protest against the extreme manner in which it is being now carried on, opinions have been freely expressed on the subject in the correspondence columns of the daily papers. Perhaps the majority of the writers were in favor of

athletics for females and thought that the views ventilated at the meeting referred to, were absurd and far-fetched. However, Miss Cowdry, one of the speakers at the meeting, "sticks to her guns" and in a letter to the *Lancet*, May 14 last, puts her point of view logically and well. She used to think that games of all kinds were good for girls, and as the mistress of a large school encouraged all forms of physical culture. Experience has caused her to change her views and she gives her reasons for this change. She believes now that strenuous games are bad for the girl and worse for the woman, and the sooner it is realized that the differences between the sexes are profound and vital and that these differences are accentuated and not lessened by evolution, the better for humanity. It would be interesting to learn the opinions of medical men, medical women, and women who are intrusted with the training of girls in America on this subject.

2. The Essential Factors of Cancer Causation.—James W. Shannon continues this discussion by considering how and why it happens that the conditions favorable to the causation of cancer (in which protozoal organisms in water play a primary part, if the theory be properly interpreted) are not present in an equal degree in all organs and parts of the body. The distinction is made between the predisposition to cancer and to lesions, the contention being that cancer results only from the cooperation of lesions and water.

2. Singultus.—Harry Schultz De Brun considers that hiccup has been sadly neglected in the practice of medicine, and that it is a symptom which physicians have passed over without determining the absolute cause. From his own study of the subject the following conclusions are formulated: (1) Singultus has been known to be the sole cause of death. (2) The symptoms may be classified as to cause: (a) Simple; (b) inflammatory; (c) irritative; (d) traumatic; (e) specific; (f) neurotic; (g) unknown origin. (3) Attacks last from one minute to several months, with or without spasms, during sleep, and with or without remissions. (4) If the condition of the patient permits, always treat the causative factor when found. (5) If physiomechanical and medicinal treatment fails, resort to narcotics and anesthetics.

9. Syphilis of the Lung Simulating Tuberculosis.—Henry M. Minton reports three cases of syphilis of the

lung which, by the casual observer, might have been diagnosed as pulmonary tuberculosis. The frequency with which these cases appear at the Phipps Institute causes him to conclude first, that syphilis of the apices of the lungs is not by any means a rare condition, and that there are many cases of this disease being treated for pulmonary tuberculosis. Second, that one should avail oneself more frequently of Wassermann and other blood tests in private practice in cases giving signs and symptoms of active tuberculosis, but not giving positive sputum. This should be done whether a history of a primary luetic lesion is obtainable or not, realizing that syphilis is often innocently acquired. Signs of an aortitis, or a perihepatitis, of weak or suppressed breath sounds, should make one suspect syphilitic infection. By pursuing such a practice there is no doubt that some cases will be arrested which are running a rapidly downward course.

4. Bronchial Spirochetosis.—W. A. Bloedorn and J. E. Houghton, holding the belief that this disease is more common in the United States than is generally recognized, and that if the nature of the infection and the possibility of encountering it were more constantly kept in mind, it would be more frequently observed, give a brief review of the history of bronchial spirochetosis, and report in full three personal observations. The organisms of spirochetel nature encountered in the sputum of these three patients more closely resembled *Spironema* than *Treponema* in that they were more refractive, more active in movement, and tended to change shape in motion. The disease, in its clinical aspects, is very suggestive of pulmonary tuberculosis, but usually can be readily distinguished from this infection. The routine examination of all sputum should include a search for spirochetes, and their presence should be regarded as significant, unless proved otherwise. The disease appears to be capable of transmission from an infected to a noninfected individual, although the degree of contagiousness is probably slight. An individual harboring the spirochetes in the sputum may present little or no evidence of the disease himself, and it appears that there exist carriers of *Spirocheta bronchialis*. The disease, as a rule, responds readily to treatment, and the arsenical preparations, particularly arsphenamine or nearsphenamine, are ordinarily very efficacious.

6. Value of the Alimentary Test in the Diagnosis of Mild Hyperthyroidism.—M. Ford Morris, in the effort to determine what value, if any, is attached to the alimentary hyperglycemia test in the diagnosis of mild hyperthyroidism—particularly in the so-called borderline cases in which the clinical signs and symptoms are not sufficient to warrant one in making a positive diagnosis, and in which it is necessary to resort to laboratory tests in order to decide what the condition is—studied ten cases in which a positive diagnosis of hyperthyroidism could not be made until the basal metabolic rate was known. These cases very properly belong to the borderline group, as far as signs and symptoms are concerned, and to the group known as mild hyperthyroidism after the metabolic rate is known. Three perfectly normal persons were used as controls for the experiment. The different tests and determinations in both normal and hyperthyroid cases were

made under the same conditions. From the results obtained in this series of cases one seems to be justified in concluding that the alimentary hyperglycemia test is of distinct value in the diagnosis of mild hyperthyroidism. In persons whose symptoms and physical findings are suggestive, but insufficient to warrant the making of a positive diagnosis of hyperthyroidism, the obtaining of results similar to those recorded in the ten cases reported may be considered as valuable corroborative evidence of the presence of thyrotoxicosis. The test, however, is not pathognomonic.

8. Significance of Diabetes Mellitus in Mental Disorders.—Horace Victor Pike states that it is not uncommon to find patients suffering from various types of psychoses who present the clinical and laboratory evidences of diabetes mellitus, in which the glycosuria appears solely as a complication of the mental disorder. These psychoses should not be confused, however, with that more uncommon group in which the mental manifestations are unquestionably due to an autotoxemia resulting from faulty sugar metabolism and in which the psychic symptoms are typical and fairly constant. During the past year he has observed, among the patients admitted to the State Hospital for the Insane at Danville, Pa., three cases of glycosuria which illustrate these two types. In these cases the intensity of the mental symptoms is in proportion to the toxemia, and improvement of the sugar metabolism is marked by a corresponding approach to normal mental functioning. When diabetes mellitus is the direct etiologic factor in the development of a psychosis, if it is early recognized and promptly treated, the progress of the mental disorder may be stayed.

3. A Contribution to the Study of Endotheliomata.—E. H. Kettle and Joan M. Ross have examined a large number of vascular tumors in the attempt to distinguish and define the characteristic features of the neoplastic endothelial cell and so place the diagnosis of the endotheliomata on a more secure basis. They have found that in tumors which can be recognized as of endothelial origin the cells invariably revert to the primitive vaso-formative type, and that this reversion is adequate to explain the structure and growth of these neoplasms. They suggest that the mere relation of tumor cells to blood vessels or to circulating blood is not conclusive evidence of an endotheliomatous origin, and that there is no evidence that the cells of an endothelioma can so closely resemble those of a carcinoma as to give rise to confusion. It is possible that this polymorphism can occur, for under certain conditions endothelial cells, especially those of serous membranes, can assume a cubical or even columnar form, but it has not been observed in any of the endotheliomata which have been examined. On the other hand, the more atypical endotheliomata progress gradually to a type of growth which is indistinguishable from a spindle-celled sarcoma. But in these, as in the hypothetical carcinomatous forms, differentiation is entirely lost, so that it is no longer possible to distinguish their endothelial origin, and there is no justification for including them among the endotheliomata. This name should be kept for tumors which reveal in their structure definite evidence of having originated from endothelium.

4. The Relation of the Liver to the Difference Value of the Blood.—Canmidge, Forsyth, and Howard consider the experimental evidence on which is based the conclusion (set forth in a previous communication) that disturbances in the functions of the liver change the relation normally existing between the difference value and the sugar content of the blood, but that when the

estimations are made at hourly intervals after a meal a difference-value curve of an entirely distinct character to that occurring in association with pancreatic insufficiency is found. They also discuss its bearing upon the original problem of their research, namely, the origin and significance of the dextrinuria of pancreatic disease, set forth in previous communications. Their summary from the present research follows: (1) The difference value of the blood, estimated at hourly intervals before and after a test-meal, follows an abnormal course in conditions where the functions of the liver are interfered with. (2) This "hepatic" curve differs markedly from the type of curve associated with pancreatic affections previously described, and bears no constant relation to the sugar content of the blood. (3) The increase in the difference value of the blood following a meal in disease of the liver is chiefly due to hydrolyzable carbohydrate, probably of a dextrin-like nature, absorbed from the alimentary tract, which is permitted to pass through the liver into the peripheral circulation instead of being retained as it is normally. (4) Dextrin-like bodies from the glycogen store of the liver may be a contributory factor in the production of the raised difference value under certain circumstances. (5) Destructive changes in the hepatic parenchyma are associated with a diminution of the amylolytic ferment content of the blood, thus tending to confirm the conclusion that the liver is the main source of that ferment.

1. An Address on Prevention and Treatment of Puerperal Infections.—W. Blair Bell, avowing that he has nothing new or striking to present, discusses the subject from a broad and practical point of view, and indicates lines of future progress. He summarizes his views as follows: (1) There must be an honest recognition by all who attend childbirth that puerperal infection is almost always avoidable, and that the appearance of it in any case that has been examined, or in which interference has been practised, is a serious reflection on the accoucheur or accoucheuse. If the whole profession would combine in an attempt to reduce the present incriminating figures a great change would be noticeable, not only in the statistics presented by the Registrar-General, but also in the health of the female population which is perpetuating our race. (2) The remedy does not lie in better teaching, so far as practitioners are concerned, but in obedience to the dictates of conscience. No man can plead ignorance of asepsis and antiseptics today. The trouble is that imperfect asepsis is practised as a sop to conscience instead of complete asepsis as a real scientific safeguard. (3) Examination per rectum with the gloved finger should be practised in the case of the parturient woman in preference to vaginal examination. Forceps delivery is far too common. Most women deliver themselves safely if left alone. Forceps delivery, when necessary, is a surgical operation, and should not be conducted in insanitary surroundings. (4) All lacerations, not only those of the perineum, must be efficiently sutured. (5) Care must be taken to maintain the natural defenses of the patient. With regard to the treatment of puerperal infections the chief conclusions are: (1) The evacuation of large pieces of placenta and efficient antiseptic irrigation of the uterus should be practised in the early stages of infection of the placental site. All infected lacerations should be purified. (2) The employment of autogenous vaccines and polyvalent serums is often useful in cases of generalized infection. (3) Major operations must be performed, especially ligation of the veins in puerperal thrombophlebitis, without hesitation and in good time when indicated.

4. Variations in the Bacterial Flora of the Upper Air Passages During the Course of Common Colds.—Arthur Bloomfield bases this contribution on certain bacteriological studies on colds made during the past winter, and upon a review of the literature. A consideration of the clinical features of colds, together with the information available in the literature, leads to the following conclusions: (1) The common cold is a definite disease generically related to grippé and influenza. The primary disease is often followed by local complications which tend to overshadow the picture. (2) Cold may produce disturbances in the upper air passages which are to be distinguished from true infectious colds. (3) None of the common bacteria found in the nose or throat have been proven to be the primary cause of colds. (4) The most convincing evidence in the literature favors a filtrable virus as the cause of the common cold. Ten individuals suffering from the so-called infectious type of acute coryza (common cold) were studied during the months of November and December, 1920. Most of the patients had the disease in its uncomplicated form, a few developed secondary local complications. The same methods as those used in studying the normal flora were employed in this work. Cultures were made at intervals during the active stage of the disease and during convalescence on rabbit-blood agar and oleate-hemoglobin agar. The swabs were taken from the nasopharynx and tonsils. Cultures were not made from the nose, because it was desired to compare the conditions with those previously studied in normals. Furthermore, in addition to draining the nasal mucous membranes, the nasopharynx was involved in all cases. The cultures were worked out in considerable detail, both quantitatively and qualitatively. On clinical grounds the view was advanced that the common cold is an infectious disease analogous to influenza, featured by the frequent development of complications in the upper air passages such as sinus infections, tracheitis, and otitis. A review of the literature showed no convincing evidence that any known organism is the primary cause of the cold. The cultural studies in the present report fail to show in uncomplicated cases any variation in the flora which would enable one to select any organism or group of organisms as the cause of colds. On the other hand, where clinical complications occurred pathogenic organisms were definitely associated with them. It is felt, therefore, that the primary cause of colds is probably an organism as yet unknown and certainly not one of the usual pathogens such as streptococcus, pneumococcus, *B. influenzae*, or staphylococcus. But the primary cold, whatever its final cause, alters the mucous membranes in such a way as to allow secondary bacterial invasion and consequent frequent development of local complications. The cultures clearly indicate that such complications are due to a variety of bacteria such as pneumococcus, streptococcus, and staphylococcus. In general it seems that the method of serial comparative study is necessary in working out the bacteriology of respiratory infections. Such a method allows one to pick out and interpret the significance of unusual organisms and also checks premature conclusions as to the etiological bearing of such organisms.

5. Hemolytic Influenza Bacilli.—T. M. Rivers and Erida L. Leuschner state that, on account of the meager descriptions given to the original *B. influenzae*, especially concerning hemolysis, it seems best to regard both hemolytic and non-hemolytic, aerobic, non-motile, Gram-negative hemoglobinophilic bacilli as influenza bacilli and disregard any such confusing terms as

"*Bacillus X*," which in itself represents not one organism but a group. After all, it makes very little difference what any one of these bacilli, non-hemolytic or hemolytic, are called, so long as everyone recognizes that they belong to the same big group.

3. Epinephrin Hypersensitiveness and Its Relation to Hyperthyroidism.—Peabody, Sturgis, Tompkins and Wearn remind the reader that two procedures are in extensive use at present in this country for the determination of functional hyperactivity of the thyroid gland, the measurement of basal metabolism and the injection of epinephrin. The diagnostic significance of the latter, to which this contribution is devoted, depends on the type of reaction which has been described as occurring in patients with hyperthyroidism, and which is supposed to be characteristic of this condition. The test is usually carried out by the method suggested by Goetsch, and 0.5 c.c. of a 1 to 1000 solution of epinephrin is administered. The "positive" reaction which has been assumed to indicate hyperthyroidism consists of the production of a rise of systolic blood pressure of at least 10 mm. of mercury or a rise in pulse-rate of at least 10 beats per minute, together with an increase of such signs and symptoms as tremor, sweating, vascular pulsation, nervousness, and palpitation. The test is so easy to apply and apparently so simple to interpret that it has been widely adopted as a diagnostic measure, and the "positive" reaction is frequently considered as an indication even for surgical interference. On account of this tendency to regard the test as highly specific in its significance, it has seemed to be of importance to study in more detail the nature of the reaction to epinephrin and to determine the conditions under which the "positive" reaction, which may be assumed to indicate epinephrin hypersensitiveness, appears. Such studies have been carried on at U. S. Army General Hospital No. 9, Lakewood, N. J., and at Peter Bent Brigham Hospital, Boston. From these observations, the results of which are briefly summarized in this communication, the following conclusions are formulated: (1) Different individuals, both sick and well, react with different degrees of intensity to the injection of epinephrin. By means of selected dosage of the drug and carefully chosen criteria for the response, one can differentiate, somewhat artificially, between the slight reactions which are called "negative" and the more violent reactions which are called "positive." In certain instances "doubtful" or "questionable" reactions are obtained. (2) The fundamental nature of the reaction is unknown. It is associated with a rise in heat production which runs more or less parallel to the intensity of the reaction. On the basis of what is definitely understood with regard to the physiologic action of epinephrin it seems probable that the phenomenon is due to a stimulation of the sympathetic nervous system. Theoretically, a "positive" reaction might indicate hyperactivity of the

thyroid gland, of the adrenal glands, or of the sympathetic nervous system. It might, on the other hand, depend on a lowered threshold of response of the sympathetic nervous system. With the exception of hyperthyroidism little is known about these conditions in man, but they probably occur and there would seem to be no reason for assuming that a "positive" epinephrin reaction is constantly associated with hyperthyroidism. It is much more likely that different causes account for the reaction in different types of clinical cases. (3) Hypersensitiveness to epinephrin is found in many patients with the clinical picture of hyperthyroidism and with an increased basal metabolism, but it is not constant under these conditions. (4) Hypersensitiveness to epinephrin is also found in persons who have no indications of hyperthyroidism. Thus it was present in many psychoneurotics in about 50 per cent. of patients convalescent from acute infections, in nearly the same proportion of soldiers with "effort syndrome" in 14 per cent. of apparently normal young men and in patients with various unrelated diseases. (5) The "positive" reaction to epinephrin appears to occur most often in highly nervous individuals, but it is not constant in such persons. The clinical significance of the reaction is not clear, but at present it should certainly not be regarded as having any specific significance in the diagnosis of hyperthyroidism.

10. The White Adrenal Line (Sergeant): Its Clinical Significance.—Willard E. Kay and Samuel Brock, from the study of 225 cases of a variety of diseases and normals, upon which numerous pharmacological and other tests were performed, feel justified in asserting that the so-called white adrenal line of Sergeant (a blanching of the skin following light stroking by a blunt object) is a local vasomotor reflex, resident in the skin, bearing no direct relationship to adrenal gland activity. The reasons for these postulations are: (a) Its independence of blood-pressure, acute fatigue and other signs of hypoadrenia; (b) its frequent occurrence in normals and in a variety of diseases unassociated with hypoadrenia; (c) its reappearance in the face of persistent general manifestations of adrenalin subcutaneously administered; (d) its peculiar association with scarlet fever. It would appear that the state of the vasomotor system which allows of its best exhibition is found in young adults of either sex, and especially in the exanthem of scarlet fever. On the basis of this series of observations it is stated that this line has not the clinical significance attributed to it. In spite of the various hypotheses evolved regarding it, further work seems necessary to establish the exact physiological mechanism of this remarkable vasomotor phenomenon.

1. The Specific and Non-Specific Immunities.—G. H. Sherman holds that a careful analysis of prevailing conditions after recovery from infectious diseases would indicate that non-specific collateral immunity is a prevailing factor in the process of specific immunization. Persons who have recovered—by which is meant that they have been completely restored to health from typhoid fever, measles, scarlet fever, or other acute infections—are not susceptible to infections for some considerable length of time as is the average individual. As a rule they enjoy exceptional good health and frequently the resistance to infection that has developed can best be explained by nonspecific immunizing responses. And this is an important natural provision. If this were not the case infections would be liable to follow one after another to an enormous disadvantage to those recovering from infectious diseases.

Obesity Following Epidemic Encephalitis.—Nobécourt mentions a case of this sequence in a girl of thirteen with the pseudo-parkinsonian syndrome. Others have seen the sequence only in subjects who made good recoveries.—*La Presse Médicale*.

Book Reviews.

ESSENTIALS OF TROPICAL MEDICINE. By WALTER E. MASTERS, M.D. Brux., M.R.C.S., I.R.C.P. Lond., Medical Officer Gold Coast, West Africa. Price, \$11.00. New York: William Wood & Co., 1920.

THIS book was planned as a digest of the knowledge of tropical medicine for the sole use of the author, but was amplified and published in book form on the suggestion of a number of professional people who had seen the earlier notes. It takes up briefly in abstract form practically all of the diseases which are considered to be characteristic of tropical regions. But in spite of the brevity of treatment none of the essential points is omitted. The work is well illustrated with numerous photographs. The book is printed in England and the use of short lines has made it rather more bulky than seems necessary. The frequency with which cases of the so-called tropical diseases are met in the temperate zone should make some such work as this a desirable addition to the library of the clinician. It is probable that this particular book would be of more use than some of the more complete and voluminous volumes on the subject which are better suited for research or reference purposes. A final section on laboratory hints contains many bits of information which will prove a valuable aid to those who are not familiar with tropical conditions.

THE GREAT WAR AND THE R. A. M. C. By Bt. Lt.-Col. F. S. BRERETON, R.A.M.C. With 9 Maps, 1 Plan, and 2 Appendices. New York: E. P. Dutton & Company, 1919.

THIS volume of nearly three hundred pages is the first of the popular medical histories of the war. It is rendered authentic by adherence to facts obtained from official papers, diaries and other basic documents. The story is told in narrative style, with enough of the "human interest" incident interpolated here and there to hold the attention of the nonmilitary as well as non-medical readers. It is rather to be regretted that the author retained the wartime use of abbreviations, for as time passes and these become less and less a matter of memory, the reader will doubtless be puzzled, if not irritated when he reads of "Lieut.-Colonel F. W. C. Jones, the A. D. M. S. of the Third Division;" of another who was "the D. A. D. M. S. of the division;" of "the K. O. Y. L. I.," part of which (or whom) contrived to escape; or of the distinguished officer who "returns to the War Office as D. G. A. M. S." Even though familiar with all these abbreviations, one would be able to read the interesting story a little more attentively if not confronted on very nearly every page with outstanding capital letters. However, that is a mere detail. The point is that the author tells in a most interesting manner the story of the splendid work of the Royal Army Medical Corps up to the time when the British Expeditionary Forces were *en route* to Flanders.

DISEASES OF CHILDREN Presented in Two Hundred Case Histories of Actual Patients Selected to Illustrate the Diagnosis, Prognosis and Treatment of the Diseases of Infancy and Childhood, with an Introductory Section on the Normal Development and Physical Examination of Infants and Children. By JOHN LOVETT MORSE, A.M., M.D., Professor of Pediatrics, Harvard Medical School; Visiting Physician at the Children's Hospital, and Consulting Physician at the Infants' Hospital and at the Floating Hospital, Boston. Third Edition. Price, \$7.50. Boston: W. M. Leonard, 1920.

STUDENTS and practitioners who delight in the "case history" variety of literature will find in this volume much to commend the manner of presentation. Barring the first sixty-two pages, which are devoted to the discursive consideration of the normal development and physical examination of infants and children, the entire volume follows the "case teaching" method adopted by the Harvard Medical School in 1900. The cases are arranged under diseases of the new-born; diseases of the gastroenteric tract; diseases of nutrition; specific infectious diseases; diseases of the nose, throat, ears and larynx; diseases of the bronchi, lungs and pleura; diseases of the heart and pericardium; diseases of the

liver; diseases of the kidneys and bladder; diseases of the blood; diseases of the nervous system, and unclassified diseases. The consideration of the various diseases under these headings involves the presentation of 200 illustrative cases, many of which are also illustrated.

ORTHOPEDIC SURGERY OF INJURIES. By Various Authors. Edited by SIR ROBERT JONES, K. B. E., C. B., F. R. C. S., in Two Volumes. New York, Oxford University Press, American Branch, 1921.

THESE interesting volumes might well serve as an encyclopedia of war surgery. They deal with all its phases. There are chapters on Precombat Training, on the splitting of war fractures from the line to the base, on the treatment of various fractures at their different stages, on osteomyelitis, on nonunion, and finally on amputations and reconstruction. Its title might almost as well be a "History of the Origin, Organization, and Services of the Department of Orthopedic Surgery in the British Army." Of particular interest are the chapters contributed by Sir Robert Jones himself, by Mr. Hey-Groves, and the collection of chapters on nerve injuries.

Although the title expressly states that the volumes deal exclusively with the orthopedic surgery of injuries it may be as well to emphasize this fact. Students and practitioners of orthopedic surgery have waited so long and so patiently for a text book by Sir Robert Jones that many of them would be likely to purchase the first books appearing under the aegis of his name, expecting a text book dealing with the subject in all its branches. This, however, it is not.

In the chapters on fractures the reader will be impressed with the simplicity of the methods employed, and with the advantages, in training large numbers of men to meet war conditions, of a more or less uniform system. This is in sharp contrast to the more individual methods of the better known French surgeons, and it is undoubtedly productive of better average results. Whether these methods will, or should supersede all others in civic practice and civil teaching, is a matter of opinion.

To readers who wish to keep fresh in their minds their war experiences, and to students who wish to prepare for the possibility of another war emergency, the volumes will be of great value. They will also find a place in the library of the industrial surgeon, and in that of the already established orthopedic specialist. The chapters on the anatomy of the peripheral nervous system, diagnosis, prognosis, operative and post operative treatment of nerve injuries make it an authoritative work of reference on peripheral nerve surgery. The size of the field covered by the various chapters is an interesting comment on the constantly enlarging scope of modern orthopedic surgery.

DERMATOLOGY. The Essentials of Cutaneous Medicine.

By WALTER JAMES HIGHMAN, M.D., Chairman Section on Dermatology and Syphilology, American Medical Association; Member of the American Dermatological Association and New York Dermatological Society; Associate Professor of Dermatology, New York Post-Graduate Medical School and Hospital; formerly Instructor in Dermatology, Cornell University Medical School; Acting Associate Dermatologist, Mt. Sinai Hospital; Adjunct Dermatologist, Lenox Hill Hospital; Pathologist, Department of Dermatology, Vanderbilt Clinic. New York: The Macmillan Company, 1921.

THIS is a book written for the general practitioner and not for the dermatological specialist; a work, as the legend on the cover reads, "which has been written from the standpoint that the dermatologist is an internist who knows the skin." It is essentially a clinical treatise, and as such devotes little space to pathology and histology. Etiology, of course, is considered, but the main insistence is upon the symptomatology and treatment. The most important and most frequently encountered lesions are pictured in ninety-five excellent illustrations, reproduced from photographs and printed on inset plates. This allows the text to be printed on uncalendered paper which is most grateful to the eyes. The descriptions of the various diseases are very clear, and the book is the best work on dermatology for the general practitioner that it has been our privilege to see in many a year.

SECTION ON MEDICINE

(Continued from page 1039.)

The Importance of the Study of Symptoms with a Discussion of Mackenzie's Law Governing Their Causation.

—Dr. FRANCIS M. POTTINGER of Monrovia, Cal., read this paper, in which he emphasized the fact that clinical observation had lagged far behind laboratory study, and that an understanding of disease required an understanding of the patient. The patient's reactions were equally as important as the laboratory reactions. An understanding of the relation of nerve stimulation to body function was of prime importance in the understanding of symptoms. Dr. Pottinger then presented a classification of the symptoms of tuberculosis and showed the part played by the nervous system in producing symptoms in this disease. Under symptoms of toxemia he classified those resulting from harmful stimulation of the central nervous system and those resulting from disturbance of the endocrine system. These symptoms were malaise, lack of endurance, loss of strength, nerve instability. Symptoms caused by harmful stimulation of the sympathetic nervous system were shown in diminished digestive activity; those caused by harmful stimulation of the sympathicotonic were symptoms of endocrine disturbance, particularly of the adrenals and thyroid, and included diminished digestive activity, increased metabolic rate, loss of weight, increased pulse rate, night sweats, elevation in temperature and polymorphonuclear leucocytosis. The hormones acted on and through the nerves. Inflammation of the lungs caused symptoms through stimulation of the parasympathetic (the vagus) and through the sympathetics. The fundamental facts regarding the vegetative sympathetic nervous system should be the common knowledge of the clinician. The nerves might be stimulated from within or from without. The symptoms of disease might be due to abnormal stimulation of the nerves through endocrine imbalance which might account for abnormal physical or psychological states, through reflex nerve action. Some symptoms of disease were produced by disturbance in normal reflexes. This was Mackenzie's conception and it had had a far reaching effect. The study of the nervous system, and particularly of the vegetative system, should be attacked with the same vigor as we were attacking laboratory problems. One could then correlate each symptom with the nerve from which it came. Thus, hoarseness was dependent upon the laryngeal nerve. Laryngeal irritation was related to the supralaryngeal nerve; cough to the laryngeal nerves. Inhibition of the heart was controlled by the motor fibers of the vagus. Increased muscle tonus and glandular secretion in the gastrointestinal canal was controlled by the motor fibers of the gastric and intestinal vagus; deviation of the tongue by the hypoglossus. Taking the sympathetotonic nerves, flushing of the face was controlled by the third sensory cervical. Spasm of the muscles of the shoulder girdle by the cervical motor nerves. Lessened motion of the chest wall was partly due to muscle spasm as above due to the cervical motor nerves, particularly the third, fourth and fifth. Deep pain in the shoulder girdle, a definite sign of tuberculosis, was due to the cervical sensory motor nerves, the second to the eighth. The degeneration of the skin and subcutaneous tissues (a matter of some importance as a symptom of tuberculosis) was governed by the scapulo-cervical, third, fourth and fifth. So in the classification of symptoms there were two factors to be taken into account, the symptoms due to toxemia and the reflexes; neither one of these alone made the diagnosis, but by their proper correlation the diagnosis could be made. If a patient had the group of symptoms designated as due to toxemia and certain of the reflex symptoms the diagnosis could be made even though some of the symptoms of toxemia were absent. Such

a classification as was reported was important because it put a bridge between cause and effect, and gave a better understanding of clinical symptoms.

An Automatic Method for Serial Blood Pressure Observations in Man.—Dr. MARION A. BLANKENHORN of Cleveland gave a lantern slide demonstration of this apparatus. He stated that it had long been recognized that it would be valuable in many conditions to be able to make repeated observations on the blood pressure at regular intervals over a long period of time with the psychical factors partly or altogether eliminated. To meet this need he had designed an apparatus to make automatic records of blood pressure, especially during sleep. It was constructed in a cabinet that could be placed at the bedside, and when connected by a tube to a pneumatic cuff on the patient's arm, made hourly tracings on a smoked drum, from which systolic and diastolic blood pressure could be estimated directly. It was constructed of simple standard laboratory equipment with the exception of the recording manometer which introduced a new principle, it being a combination of the oscilometer and manometer.

Dr. PAUL D. WHITE of Boston expressed the opinion that this instrument gave a great opportunity for further investigation not only of blood pressure during sleep but under other conditions, and it certainly gave a great opportunity for blood pressure experimentation. During the war they had used the oscilometer method which gave abnormally high readings. Owing to its less delicate mechanism this instrument did away with this inaccuracy. He thought Dr. Blankenhorn had given them a valuable instrument for determining the diastolic as well as the systolic blood pressure.

Dr. PLUMMER said this apparatus interested him because he had frequently felt the need of a method for determining the blood pressure during sleep. It certainly opened up an important field for investigation for which up to the present time they had had no apparatus which was suitable.

JOINT MEETING OF SECTIONS ON PRACTICE OF MEDICINE, PHARMACOLOGY AND THERAPEUTICS, AND PATHOLOGY AND PHYSIOLOGY.

Second Day—Thursday, June 9.

Chairman's Address—The Interrelationship of the Thyroid Gland and of Its Active Agent, Thyroxin, in the Tissues of the Body.—Dr. HENRY S. PLUMMER of Rochester, Minn., delivered this address, in which he gave a comprehensive review of the investigations leading up to the discovery of thyroxin by Kendall, and followed the development of their work from that time to the present, emphasizing the importance of metabolic studies, inasmuch as they formed the basis upon which elaboration of the thyroxin in the thyroid and its delivery to the body could be estimated. There was no evidence that the thyroid had any function other than the elaboration of thyroxin and furnishing it to the body. Thyroxin acted directly or indirectly upon the cells throughout the body, being perhaps the chief factor in the excitation of cellular activity. Dr. Plummer defined hypo- and hyperthyroidism, and reviewed his classification of thyroid diseases. He emphasized the point that the severity of symptoms in exophthalmic goiter was not due to the amount of hypertrophy in the gland but to the amount of hyperthyroidism. From his studies it might be drawn that after the administration of known quantities of thyroxin sufficient to bring the basal metabolism to normal the basal metabolism remained about normal for ten or twelve days and then returned to its previous status in from five to eight weeks. Kendall had estimated that the amount of thyroxin in the tissues of the body normally was about 14 mgs. The thyroid in approximately a normal individual maintained a very constant amount of thyroxin in the body, which was somewhat different from our knowledge of the products of the body generally. It was assumed that the thyroid had a definite known action on the other agents of the body without knowing the exact mechanism by which it acted. It had been found that in the normal individual in whom the thyroid was supplying a very constant amount of thyroxin to the body the daily administration of one milligram of thyroxin daily would place the thyroid at rest. They had given one milligram of thyroxin daily

in this way for months without producing a change in the basal metabolism rate or any physical disturbance. On this basis the dose for myxedematous patients could be regulated to meet the needs of the individual patient. There was much evidence to suggest that the rate of exhaustion of thyroxin was much more rapid in the female than in the male. The constant manner in which the administration of thyroxin was followed by elevation of the basal metabolism left no doubt as to the definite relation between the metabolic rate and thyroid activity. Whatever might be the significance of hyperthyroidism in exophthalmic goiter it had no definite relation to pregnancy and adolescence. Marine's work had shown definitely that small doses of iodine administered to young people living in endemic goiter localities prevented the development of the condition, and also apparently controlled adolescent colloid goiter. Evidence had been collected that went to show that it was the adenomatous tissue that hyperfunctionated. Once this tissue had started to hyperfunctionate it continued to do so erratically and without regard to the needs of the individual. Through the entrance of toxic material into the intestinal tract a change in the intestinal flora might be brought about which would interfere with the small amount of iodine available. This relationship of the intestinal flora to the small iodine content of the intestine might explain the geographical distribution of exophthalmic goiter. In closing, Dr. Plummer said that taking the theme as he had presented it it was apparent that a lack of assurance in childhood might cause a mild hyperthyroidism which would lay the foundation for a colloid adenoma in adolescence and of hyperfunctionating adenoma in old age.

Fundamental Ideas Regarding Basal Metabolism.—Dr. GRAHAM LUSK of New York reviewed the literature in connection with oxygen absorption and heat production and noted that it had early been observed that oxygen absorption and heat production went on much more rapidly in small animals or birds than in larger animals. He then went on to trace the development of the law of surface area and demonstrated the principle that caloric estimations should be expressed in terms of surface area and not in weight, inasmuch as we had no means of estimating the protoplasmic mass. He traced the development of Du Bois' work showing that the measure of the basal metabolism in a normal individual was 40 calories per square meter of body surface per hour for men and about 7 per cent. less in women. Du Bois had found that there was no decline in the metabolic rate due to old age. The differences of the results by the different methods devised for the estimation of the basal metabolism did not show a great variation in results, so that to-day the main controversy centered not around methods but around the interpretation of results. The establishment of a predictable basal metabolism on the basis of the relation of surface area to heat production now made possible the interpretation of variations from the normal in many diseased conditions and offered a method now widely accepted for closer clinical diagnosis in several pathological conditions.

The Measurement and Standards of Basal Metabolism (Lantern Demonstration).—Dr. FRANCIS G. BENEDICT of Boston made this presentation, in which he stated that the measurement of basal metabolism had, by a new technique, been brought from the special research laboratory to the hospital. It was not feasible for the busy clinician. It was not easy. Training in the technique and especially in the interpretation of results was essential, if pitfalls were to be avoided and, indeed, if real harm from misinterpretation of results was not done. With the wide distribution of portable apparatus for the estimation of the basal metabolism it was important to establish a normal average with which to compare pathological data. In making the basal metabolism observation of the patient the time selected must be twelve hours after the last meal, the patient must have been in complete muscular repose for at least one-half hour before the test was begun, the room temperature should be about 20 deg. C., and any febrile condition must be ruled out. Basal metabolism was affected independently by height, age, weight and sex. Standards should consider all these factors. Variability was large even among normals, hence fixed

standards should be used only guardedly. To the ordinary factors of height, age, weight, etc., two measurements had recently been added. One of these was the sitting height emphasized by Dreyer and the other was the sitting height to the supra-sternal notch. With the perfection now developed in the actual tests, the difficulty had shifted to the interpretation. An intelligent high school girl might be trained to make the tests, but their interpretation was another matter. Dr. Benedict presented two mathematical equations, which had recently been published, upon the basis of which the predictable basal metabolism could be estimated in any individual. Between the ages of twenty and forty the predictable error was small. Outside of this range the prediction should be made only with great care. The predictable basal metabolism in women could not be made with anything like that in man. Before attempting to use the basal metabolism it behooved every physician to gain as much information as possible both as to the technique of the tests and the interpretation of results. Medical schools should admit to the curriculum our present knowledge of this subject as was being done at Cornell Medical College under Dr. Du Bois.

The Basal Metabolic Rates in Hyperthyroidism (Lantern Slides).—Dr. WALTER M. BOOTHBY of Rochester, Minn., made this contribution, in which he showed that exophthalmic goiter and adenoma with hyperthyroidism were two distinct diseases. Both syndromes had common symptoms caused by increase in the basal metabolic rate. Because similar symptoms followed the administration of large doses of thyroxin and as the only known effect of thyroxin was to cause an increased basal metabolic rate, symptoms produced by a hyperfunctionating adenoma were fittingly designated hyperthyroidism. Exophthalmic goiter, while it had these same symptoms that were dependent upon an increased metabolism, yet had in addition definite typical symptoms which characterized the disease and yet could not be produced by an excess of thyroxin. There was an increased metabolic rate in acromegaly and a decreased rate in hypopituitarism. An alteration in the pituitary gland might change the metabolic level but there was no evidence that it acted as an oxidizing or catalyzing agent. He deprecated the tendency to parcel out to each ductless gland a certain definite function entirely hypothetical such as was evinced in much of the current literature on endocrinology. Exophthalmic goiter was differentiated from adenoma with hyperthyroidism by the fact that in exophthalmic goiter there was the thrill and bruit, a tendency to gastric crises, and also a peculiar type of nervousness. There was a difference in the mode of onset, the clinical course, the physical signs, and a difference in the pathology of the thyroid gland. To account for the difference the theory had been advanced that in exophthalmic goiter the thyroid cells were producing not only an excess of the thyroid hormone but that the secretion was so formed that it possessed some peculiar property different from normal thyroxin. Kendall had suggested a slight alteration in the thyroid molecule. Aside from the academic interest attaching to the question the differentiation of the two diseases was important because the operative procedure was different in exophthalmic goiter from that in thyroid adenoma. In adenoma the operation was directed to the removal of the tumor while in exophthalmic goiter it was directed to the reduction of the over-activity of the gland by successive steps, as the injection of hot water, ligation, and one or more partial thyroidectomies. In exophthalmic goiter the benefit from ligation was usually quite marked. In adenoma simple enucleation of the adenoma was usually sufficient to effect a cure, but resection was necessary to reduce the hyperplastic parenchyma of exophthalmic goiter within normal limits, and sometimes a second and a third partial resections were necessary before the cure was complete. They had been unable to prove that the x-ray influenced the natural course of exophthalmic goiter. It was obvious that a sharp distinction could not be drawn between mild cases of exophthalmic goiter and effort syndrome on a clinical basis, but here the basal metabolism was useful if small errors were carefully excluded inasmuch as the basal metabolism was not elevated in the effort syndrome if other conditions were excluded, since the thyroid hormone was not increased. The adrenalin re-

action Dr. Boothby considered of no aid in differentiating hyperthyroidism since it was present in a large percentage of individuals not suffering from hyperthyroidism and even in cases of myxedema.

Determinations of the Basal Metabolism as an Aid to Diagnosis and a Guide to Treatment in Various Diseases (Lantern Demonstration).—Dr. JAMES H. MEANS of Boston read this paper. He stated that indirect calorimetry, thanks to the work of Du Bois and Benedict, had come into wide use in American clinics as an important test of function. The importance of accuracy of technique could not be too greatly emphasized. Like any functional test it had its limitations. These should be constantly borne in mind. In the differential diagnosis of hyperthyroidism from neurasthenia, effort syndrome and afebrile tuberculosis, in the detection of myxedema and more particularly atypical hyperthyroidism, a knowledge of hyperthyroidism was very helpful. It was useful also in the differentiation of toxic from nontoxic goiters. There were differences in metabolism not explained on the basis of size, weight, form, etc., but these differences were slight as compared with the changes that were found in disease. We were familiar with a number of constants which were relative constants. The blood was one of the most important of these constants. Other constants were body temperature, pulse rate, respiratory rate. We were all familiar with the normal variations in pulse rate; the same reasoning that applied to variations in pulse rate applied to variations in metabolism, though the basal metabolic rate was more constant than the pulse rate, and therefore it was a more accurate means of determining function. In interpreting the significance of the basal metabolic rate one must correlate it with the physical findings exactly as one interpreted laboratory findings, the x-ray, blood sugar, phtalein excretion, etc. In warning against inaccuracy of technique, Dr. Means said that instrument makers were exploiting various forms of apparatus for the estimation of the basal metabolism and saying that the clinician needed an apparatus for the estimation of the basal metabolism quite as much as he needed a stethoscope. He had frequently been asked by practitioners if they should set up a metabolism laboratory. He told them he could not see that they were under any obligation to do so, that it depended upon their needs. The up-to-date clinician made a Wassermann test, but he could not see that there was the same necessity for the estimation of the basal metabolism. To him the determination of the basal metabolism was less important than the determination of the temperature in typhoid fever; it was better not to make it than to make it inaccurately, though if one had the facilities for making it a knowledge of the basal metabolism would often be a help. In the differentiation of borderline cases it was often very valuable, and as an aid in directing the treatment of hyperthyroidism. Here the metabolic chart had a value comparable to that of a temperature and pulse chart in typhoid fever or pneumonia, the difference being that it extended over months instead of over weeks or days. In exophthalmic goiter cases the metabolic rate ran parallel with the pulse rate and body weight. A gain in weight and a fall in pulse rate was accompanied by a fall in the basal metabolism. With the use of the x-ray just short of an erythema dose, and no other treatment except rest, there was in many cases of exophthalmic goiter a fall in the basal metabolism. This, however, did not occur in all cases. In cases of hypothyroidism the basal metabolism could be raised to normal by the administration of thyroid. The basal metabolism outside of the thyroid states did not play a large role in clinical medicine at the present time, but was valuable in research. One other direct clinical application was in obesity. In simple obesity the basal metabolism was normal, that was where the obesity was due to food intake. The administration of thyroid in such cases produced hyperthyroidism and its effect was pernicious; it relieved one fault by substituting another. He had been impressed by the use of thyroid in obesity by the laity. It should never be given except in the presence of a low basal metabolism. In tuberculosis without fever and neurasthenia the basal metabolism was not elevated.

The Basal Metabolism of Fever.—Dr. EUGENE F. DuBois of New York presented this contribution, in

which he stated that there was a striking similarity between the phenomena of heart regulation in malarial paroxysms and in the chills which followed the administration of foreign protein. In the acute infectious diseases with equal degrees of fever the basal metabolism was increased about the same percentage. In chronic fevers such as tuberculosis the basal metabolism was not as high as in acute infections. As causes of a high metabolism increased temperature, toxemia, and abnormally high protein metabolism must be taken into account.

Dr. GEORGE W. CRILE said it had seemed to him in listening to the papers that these sections had established an epoch in the application and correlation of the best science of medicine and surgery. It must be very gratifying to Dr. Lusk, Dr. Benedict, and Dr. Atwater to know that their work was so highly appreciated by the leaders in medicine and surgery. Dr. Crile confined his discussion to three points: First, Dr. Boothby had made the statement that in his observation he was not able to say that the x-ray controlled exophthalmic goiter. He gave his entire assent to that statement. He had seen no great benefit from the x-ray, and where there appeared to be a temporary improvement it was followed by a recrudescence as a rule. He did not believe the x-ray was the permanent answer to the question of treatment of exophthalmic goiter. Second, he did not think that at the present time we had data sufficiently accurate upon which to base a classification of exophthalmic goiter. He did not think the basis of classification was safely placed upon the histology of the thyroid gland. He did not think that in early cases or exceptional cases it was possible to make a classification on the basal metabolic rates. In their clinic they had operated upon quite a few cases of exophthalmic goiter that did not show an alteration in basal metabolism and yet they had obtained good clinical results. He believed the most important thing was still careful history and physical examination, and after that it was of great importance to consider the basal metabolism, but it should not be considered as pathognomonic. A third point was that he was glad to hear Dr. Boothby say that the basal metabolic rate was not the true guide upon which to project an operation. He thought the best guide was the judgment of the surgeon and the physician. For example, one might know the basal metabolic rate but that did not give information with reference to the reserve in the myocardium, or the liver, of the central nervous system. Finally, if surgery was to avail its effect upon the patient must be minimized. One could always ligate one thyroid artery with local anesthesia, with quinine hydrochloride and urea, and thus block the patient into semi-consciousness. The fact that their mortality rate was one in 250 ligations, and that they had a series of 225 ligations still unbroken spoke for the value of this procedure. Then after three months the patient might return for a second ligation or a sub-total thyroidectomy if he was a bad risk for a primary operation. Their operative mortality without taking basal metabolic rates was 1.2 per cent. Upon those grounds he urged surgeons to be more careful and to do the work much more gradually and then the reaction upon the patient would be less than the reaction upon entering the hospital, and if he lived through his entrance into the hospital he ought to live through litigation.

Dr. PLUMMER emphasized the point that one should avoid the error that the metabolism rate was an index of operability. It merely indicated the status of the patient. It was merely a form of measure which told us something of the patient's condition.

Dr. CHARLES MAYO said the program of the morning had been very interesting and profitable as presented by the men who had "put metabolism on the map." It had been interesting to hear the theory and development of metabolism for a hundred years. It had taken more than fifty years to devise the apparatus with which accurate observations could be made. Twelve hundred doctors had listened during the morning because of their interest in metabolism and to find out what applications it had in those chronic diseases which had been discussed, and particularly to those of the thyroid. He went on to show that the discovery of thyroxin by Kendall and his subsequent

work had shown that thyroxin was not only a causative agent of combustion in the body but it was the most important one we had. It concerned old age and youth and the decades between. Without the thyroid we would have no development, or at least we would revert to a myxedomatous state. With thyroxin one could bring the myxedomatous individual to normal and carry him beyond. Dr. Kendall's work had enabled them to know just the amount of thyroxin that the body burned and the exact amount needed to bring various degrees of efficiency up to normal, and just how long it took for a certain amount to burn out. Having found thyroxin it might not be far to travel before they would be able to subject other glands to the same searching processes. Dr. Mayo said he would rather operate on a patient newly come down with hyperthyroidism, who had not lost weight with a metabolic rate of 76 than upon one with a metabolism of 46 who had been continually using up his tissues, since the degree of disease was not told by the metabolism, but by the degree of burning. Thyroid conditions and exophthalmic goiter had gotten well without treatment and without operation, and he had seen two cases of cancer of the neck due to x-ray used in the treatment of thyroid conditions. Those things could be avoided by remembering that the x-ray was something we could not regulate. The idea of operation was to remove the over-active thyroid or a part of it. Some operations failed because of not having sufficient tissue removed to bring the metabolic rate down. Dr. Mayo deprecated bringing in the neuroasthenic. He thought enough was known now to employ epinephrin, since the changes it brought about indicated the degree of stability or instability of the nervous system and if one operated on a case in which hyperthyroidism was diagnosed on that basis he was operating on a psychoneurotic condition, which was on a parallel with going back to the use of Hunter's method of dilating the lower ureter or the removal of the left ovary for a neurotic condition.

Dr. J. C. AUB of Boston stated that unquestionably thyroxin increased the metabolic rate and as Dr. Plummer had expressed the idea, it increased the metabolic rate because it increased the oxidation of the cells. He and his co-workers had been trying to find whether increased muscle tonus increased the metabolic rate. To determine the influence of muscle tonus they had found the metabolic rate in anesthetized and non-anesthetized subjects and they had found that the metabolic rate was the same in both. The basal metabolism was not under the control of the peripheral nerves because if the peripheral nerves were cut it did not fall. These facts indicated that it was the thyroxin that did the work of increasing the basal metabolism and that it was not produced by the tremor often found in hyperthyroid conditions.

Dr. FRITZ B. TALBOT of Boston said that although the discussion had been confined to metabolism as it related to adults he felt that it was in place to bring out of two points in regard to basal metabolism in childhood. First, it seemed that the true basal metabolism could not be obtained in children under two years of age with a mouth and nose piece. It surely could not be obtained in a child of six years, and consequently he would warn against any interpretation of findings from an apparatus using a nose and mouth piece on young children and in older children with the exception of those who were thoroughly trained or where there was no element of excitement and the child was absolutely quiet. The interpretation of the results was fraught with many more dangers in children than in adults for the reason that childhood and infancy was the period of change and the standards used must be changed accordingly. There was an increased metabolism during the first one and a half or two years of life. Another point in regard to malnutrition; malnutrition in infancy was quite different from malnutrition in the adult. Two or three of the speakers had said that in malnutrition one must expect a lower metabolism; in malnutrition in infancy the basal metabolism was increased, sometimes 50 to 60 per cent above normal. In regard to the subject of hypo- and hyperthyroidism, Dr. Talbot stated that he had studied two infants who clinically were early cretins; one had a metabolism of minus 18 and the other had a normal metabolism. He was unable to explain it except that

theoretically the mother might give enough of the thyroid element to supply the infant for a time and the clinical evidence of the condition appeared before the metabolism changed. The statement had also been made that there was no change in the basal metabolism at puberty. Two or three of Benedict's and his cases showed an increased metabolism at puberty. He had the idea that of the children who had palpable thyroids at puberty two-thirds of them would be found to have increased metabolism.

Dr. BENEDICT said that being untutored in matters medical he was particularly interested in Dr. DuBois' work. He would like to know in his remarkable correlative of temperature of the body and heat production whether the temperatures used were rectal temperatures or the whole average body temperature.

Dr. BOOTHBY said in regard to the discussion on surface area, they had found that exceedingly accurate in their clinical work. They had found that of normal people coming to the clinic a great proportion fell within five per cent of variation of the normals published by Dr. Lusk. In 21,000 estimations done by them they hardly ever found a case with an abnormal metabolic rate that did not have a reasonable clinical explanation. In regard to Dr. Crile's statement about the cases of exophthalmic goiter with normal metabolic rate, it was obvious that some other factor beside the exophthalmic goiter entered in and influenced the rate.

Dr. MEANS said with reference to estimation of body surface and heat production, he had recently completed a comparative study of the different calorimeters in use and it did not seem to him that it made much difference which one was used. As to the x-ray treatment he did not wish to enter into a discussion of that subject except to say that they believed that in certain cases under x-ray treatment there was a more rapid fall in the clinical symptoms and also in the metabolic rate than one could expect in the course of a spontaneous recovery. As to the matter of recrudescences, there were recrudescences seen after other modes of treatment; recrudescences were seen after surgery, and after fairly complete operation. So that he did not believe that the fact that a recrudescence occurred meant that the x-ray should not have a place in the treatment of hyperthyroidism. The x-ray had been objected to on the ground that it produced myxedema in some cases. That was proof that the x-ray was effective, and if myxedema was produced it was an easy matter to administer thyroid. It might also be mentioned that myxedema had been known to occur following surgery, so one could scarcely give that as a reason for not using the x-ray; as a rule the myxedema followed the use of the x-ray was only temporary.

Dr. DU BOIS spoke of the body temperature. He said that practically we never could tell the exact body temperature. However the variation from the exact temperature was very small excepting at periods when there was a very sudden rise of temperature. The correlation was made with the rectal temperature.

Dr. J. E. ELSE of Portland, Ore., stated that during the last year and a half he had reviewed cases in which these three methods of estimating the basal metabolism did not coincide. He had grouped the cases with an approximately normal metabolism into (1) those who had a small goiter and very mild symptoms but had some other condition as, for instance, tonsillitis. Here he would take exception to the statement that the estimation of the basal metabolism was not necessary; (2) A group of cases in the stages of remission. During remission one might find the basal metabolism about normal but here the clinical findings and pathology did not coincide with a basal metabolism; (3) a class of toxic goiters which were rather severe and in which the patient recovered so far as the thyroid gland was concerned, but a permanent lesion remained in the heart. In these cases the tumor might remain and there might be mental irritability, but the metabolic findings would be normal because there was no longer a toxic goiter present.

Dr. ALBERT ROUSSEL of Philadelphia disagreed with the speaker who had minimized the value of estimating the metabolic rate. He thought that many cases of hypothyroidism were unrecognized. The estimation of the basal metabolism was as essential in these cases

as a study of the blood chemistry in the various forms of nephritis. A study of the basal metabolism was an important adjunct to the practice of medicine as were other methods of precision, and, like other methods of precision, it had its limitations. He had been particularly interested in the decrease of metabolism under the x-ray. He had reported marked improvement and cure in cases of toxic goiter that had persisted for four or five years as the result of treatment by intensive doses of x-ray. Perhaps the lighter doses had the opposite effect. The fact that x-ray treatment might produce myxedema was the best evidence that the x-ray treatment of toxic goiter was effective.

Dr. PLUMMER emphasized the point that it was a fallacy to try to associate the degree of thyroid activity with pathological pictures. In exophthalmic goiter the hypertrophy might vary all the way from the vanishing point to a most intense hypertrophy. In the human being one did not see the same hypertrophy of the thyroid gland that he had seen in animals with the slightest provocation. In no instance could they associate exophthalmic goiter with puberty or pregnancy or other conditions; it was a distinct entity, though there were borderline cases that could not be definitely differentiated. In some borderline cases the metabolism was normal whether the condition was hypo- or hyperthyroid. In all their series there were some exceptions to the rule. There were cases of exophthalmic goiter in which the basal metabolic rate dropped nearly to normal. It was possible to have perversion in the gland without disturbance of function, or hyperthyroidism might be present and other factors might be holding the metabolism down. In closing, Dr. Plummer brought out the point that to one who saw many of these cases they naturally fell into groups without forcing the grouping, though what the meaning of the grouping was he did not know.

Third Day—Friday, June 10.

Truer Standards in the Diagnosis of Heart Failure: A Hitherto Unemphasized Form of Arrhythmia.—Dr. HARRY WIEL of San Francisco made this presentation, in which he said that many men meant different things when they spoke of heart failure. There was a distinction between heart disease and heart failure. Dr. Alfred Cohn's definition of heart failure boiled down was that it was a condition in which the heart and circulation failed to support the individual in that condition of life which he led. The paper was based on six months' work in a cardiac ward. The writer's impression before undertaking the study was that nearly if not all heart failures showed abnormal rhythms. He had endeavored to find out if close analysis would confirm this. In watching cases as they came into the hospital, it could not be emphasized too often or too strongly that the crux was "what was the myocardium capable of doing?" The function of the myocardium was the thing to be studied mainly from the clinical standpoint. Heart disease did not necessarily involve heart failure nor did myocardial involvement necessarily involve heart failure. In this study it was soon observed that the cases fell into four groups: Heart disease other than failure; out and out failure without question; so-called cardio-renal cases; cases presenting symptoms of heart failure and classed as such because no pathology was found elsewhere. The first group did not fall within the purposes of the present discussion. The second group were those having auricular fibrillation, and in this group the most striking thing was the behavior of the edema. He thought we were getting over the idea that there was no edema in heart failure. One of the patients falling in this class presented an enormous amount of edema and another presented none at all. He recalled several patients with enormous edema who, as they progressed to death, lost their edema and became emaciated. On the other hand some who came into the hospital without edema died with a pitiful anasarca. It had occurred to him that in these cases one must look elsewhere than in the mechanical factors for the production of edema. It seemed that for the explanation of the edema they would have to look along the lines of blood chemistry and metabolism. Taking the third group, the so-called cardiorenal cases, he thought this term was very loosely used. The cases with characteristic urinary findings, low functional

tests, an excretion of phthalein below 20, hypertension, rapid pulse, and arteriosclerosis, commonly had a failing myocardium and should be handled accordingly. The last group were those cases which presented the so-called cardiac trilogy, edema, cyanosis and dyspnea. They could be divided into two groups: (a) Cases simulating heart failure, but not such; (b) cases showing on ordinary examination no arrhythmias, but on closer study an interesting arrhythmias not readily detected. To illustrate the first group he cited a case presenting the usual symptoms of heart failure in which the patient was later found to be suffering from carcinoma of the stomach. The second group of cases showing no arrhythmias at first but if electrocardiographic tracings were taken might show a regular time rhythm but an irregularity of amplitude. The suggestion was offered that this might be due to a serious defect in contractility though he did not wish to make this statement in a dogmatic way. The point he emphasized was that heart failure when well established must not be predicated from findings other than in the heart itself. The situation was different with beginning heart failure.

Dr. PAUL WHITE of Boston pointed out certain features in the electrocardiograms which led him to believe that they did not show a true pulsus alternans but a pseudo pulsus alternans. It was possible that the variations in pressure due to the respiratory phase had not been taken into consideration. He did not think one could draw conclusions as to the condition of the myocardium from such tracings as were shown, as the myocardium might be irritable without being diseased; such tracings gave evidence of irritation of the myocardium but not of disease.

Dr. WILLIAM D. REID of Boston emphasized the importance in the diagnosis of heart failure of going back of the structural lesion.

Dr. W. S. PLUMMER called attention to an interesting relation between auricular fibrillation and edema in hyperthyroid states. Temporary auricular fibrillation was common in hyperthyroidism. It was a common occurrence to have a heart fibrillate for three or four hours, or even for a half hour, with evidence of increased basal metabolism. That might occur immediately following operation. It was not at all rare to see cases fibrillate for two or three months and then thoroughly recover. More interesting still was the fact that a case might fibrillate for two years and then cease to fibrillate. He had seen hearts fibrillate for a few hours following the administration of thyroid. Another interesting observation in regard to the edema was being made in a large series of cases of hyperthyroidism with high basal metabolism. There was a large amount of work opening up in these directions. At the present time they were only on the periphery of what was opening up in these directions. In the presence of a high basal metabolism the heart was doing more work than it was called upon to do under moderate stresses and under these conditions it was easy for edema to develop. The demand made upon the heart in hyperthyroidism even when the patient was at rest in bed was far greater than that made upon a normal individual in bed.

Dr. WIEL, in closing the discussion, stated that their records had made due allowance for the variations due to difference in the respiratory phase.

Observations on the Heart in Diphtheria.—Dr. S. CALVIN SMITH of Philadelphia read this paper, which was based upon a study of 242 cases of diphtheria in the Philadelphia Hospital for Contagious Diseases, in 1920. If this series of cases 72 per cent. progressed without evidence of cardiac disturbance; the other 28 per cent. exhibited heart irregularities. Of these pulse abnormalities, 65 per cent. consisted of sinus arrhythmia and of a condition called sino-auricular block, both of which were probably without pathologic significance; 20 per cent. consisted of premature contractions, those of auricular origin predominating; the remaining 15 per cent. consisted of high grade heart block of sudden inception about the seventh day, which rapidly deepened into coma, death promptly resulting within thirty-six hours. Heart block was the only cardiac abnormality which resulted in death; in this series of cases it invariably terminated fatally. All other types of irregularity recovered. The four factors

which led them to expect heart block in diphtheria were: 1. Constitutional inferiority malnutrition, depletion following infectious disease, etc. 2. The amount and time in hours between the onset of the disease and the administration of antitoxin in therapeutic doses. 3. The degree of toxicity at the time of the administration of antitoxin. 4. The prolongation of the initial tachycardia over several days. The heart block coming on at about the seventh day was characterized by sudden onset. The patient was conscious, showed great pallor with a peculiar blanching around the mouth, the pulse was of low volume, the precordial impulse was low, Cheyne-Stokes respiration was more often absent than present. There was a precipitate fall in the pulse rate and the appearance of the patient was that of pronounced circulatory urgency. In the heart block of diphtheria digitalis was distinctly contraindicated. In the minor irregularities the drug might stimulate ventricular contraction but it decreased the cardiac reserve so that the heart might be in danger of attack by the diphtheria toxins still in the body. Heart abnormalities in diphtheria were usually manifested in disturbed conductivity reflected in the pulse rate. Acute heart block was not observed once in the early course of diphtheria and there was every reason to believe that if antitoxin were administered early this complication would not occur later.

Dr. E. H. PLACE of Boston stated that the paper had clearly and very concisely shown the disturbances of the heart in diphtheria. He disagreed, however, with a statement made regarding the factors predisposing to heart block, that was that the constitutionally inferior child was more liable to develop heart block in diphtheria. In his experience it was the superior individual who had been injured by diphtheria, and the same he had found true in most of the acute infections of childhood. One of the peculiarities of heart block following diphtheria was the suddenness of its onset usually from the seventh to the twenty-first day and the completeness with which recovery occurred in the cases that did not die was likewise striking. Death almost always occurred but there were a few cases that recovered. If the child survived for two weeks after the symptoms of heart block developed its chances for recovery were good. Recovery undoubtedly occurred even in marked cases, though unfortunately this statement was open to question since they had not had the facilities for making electrocardiographic tracings at the City Hospital. Even where very marked changes had been present recovery was complete, the electrocardiogram showing no abnormality. Their experience in the treatment of heart involvement in diphtheria coincided with that of the reader of the paper so far as digitalis was concerned. The only help could come from an attempt to lighten the work of the heart. The best treatment was that which kept the patient at his minimum of metabolism. He should be given nothing by mouth, but should be given water by rectum. Morphine should be used in small and often repeated doses to keep the patient quiet and comfortable. In their service the mortality from heart complications was from 50 to 85 per cent. Some series ran lower. Dr. Place said he wished to emphasize the point brought out by Dr. Smith that treatment was of little avail and that prevention was easy if they got the case early and administered antitoxin in large doses within twenty-four hours. Those patients who had had diphtheria two or three days or longer were likely to suffer from this complication during convalescence. The clinical manifestations gave as reliable indication of the presence of this complication as did the electrocardiogram.

Dr. ALEXANDER LAMBERT said he would like to ask Dr. Smith and Dr. Place with reference to a type of irregularity seen in adults following diphtheria oftener than in children; that was that the pulse ran at a fairly normal frequency when the patient was quiet, but mere rising would send it up to 160 or 170 per minute. He saw that many years ago before the introduction of antitoxin, and recalled an instance in which in one family there were four children between the ages of sixteen and twenty years who had this form of tachycardia, and all recovered. He asked whether the vagus was injured or whether the injury was to the contractile system rather than to the conductive in heart block in diphtheria.

Dr. MILTON H. FUSSELL of Philadelphia emphasized the time relation and dose of antitoxin to heart failure in diphtheria. He said they were all prone to put off the time of the administration of antitoxin. It was better to administer the antitoxin when the diagnosis was uncertain than to wait until the diagnosis was certain when the delay in the administration of antitoxin might lead to fatal cardiac complications.

Dr. PAUL WHITE of Boston said that in view of the work that had been done in the study of cardiac complications in diphtheria he thought we must make a place in the classification of heart disease for the heart disease of diphtheria, and that one must occasionally make the diagnosis of diphtheritic heart disease.

Dr. JOHN H. BLODGETT of Bellows Falls, Vt., asked what the significance was of the symptom known as *bruit de gallop*, and what the dose of antitoxin Dr. Smith was giving.

Dr. WILLIAM H. BLOCK of New Orleans emphasized the point that it was extremely important that an early diagnosis should be made in diphtheria, and that antitoxin be given as early as possible. He asked the essayist what relation the time of the administration of the antitoxin had to the outcome of the cases in this series.

Dr. CALVIN A. SMITH in closing the discussion, said he had evidently created the impression that all cases of heart block in diphtheria terminated fatally. The cases in his series had all died but he did not mean to say that there were not some cases that might recover. Dr. Lambert had spoken of the pulse being quiet when the patient was at rest and then upon standing a sudden tachycardia would appear. He had been unable to select records of cases of that kind. As to the ordinary dose of antitoxin given in the Municipal Hospital, it was from 15,000 to 30,000 units given intravenously in cases severely or moderately ill. Sometimes in the mild cases the antitoxin was given under the skin, but in the severe cases always intravenously. The *bruit de gallop* he had never succeeded in identifying; it might be a bundle branch block but he had never succeeded in identifying it by the tracings.

Principles Underlying Treatment of Heart Disease by Exercise (Lantern Demonstration).—Dr. THEODORE B. BARRINGER of New York presented this contribution. He stated that the idea prevailed that the chief cause of heart disease was physical overstrain with the result that exercise had been almost completely banished as a therapeutic measure in the treatment of heart disease. In an analysis of 154 cases of heart failure in which there was valvular or muscular involvement or both there were but three cases in which there was any evidence of severe sudden strain being a causative factor. In 151 cases there was fever and polymorphonuclear lymphocytosis. Fever and leucocytosis in patients with heart failure had generally been considered to be due to pulmonary congestion or to general venous congestion. This idea was at variance with the teachings of the newer circulatory physiology and with clinical experience, but in addition, a study of this series of cases gave grounds for the belief that fever and leucocytosis were evidences rather of an infectious process in the heart itself which had caused the heart to fail. A study of the circulatory physiology showed that during physical work the heart increased its output, the splanchnic vessels were restricted and the blood pressure rose. Both the coronary flow and the flow in the general circulation increased during exercise; it might be increased even to six times its normal rate. This increased blood flow must have an effect upon nutrition, and an improvement in nutrition improved the contractile power of the muscle tissue, including the heart. Hence, as a result of the exercise the cardiac reserve was increased. In a normal man after exercise the blood pressure would go up, but it subsided very quickly afterward. Interpreting that in physiological terms, the rise in blood pressure was due to the heart contracting more energetically and causing an increased output while the splanchnic vessels were constricted. In a case of cardiac disease with a large cardiac reserve the results were the same. If there was a small cardiac reserve the reactions would be different, there being a delayed rise in blood pressure, a prolonged fall and pulsus alternans. When that phenomenon occurred it furnished evidence that the

heart had been overtaxed. They had found that patients with a limited cardiac reserve were able to work for shorter periods of time and could not work as rapidly as normal individuals. There were a number of indications by which the exercise tolerance could be determined. Of these the form of the systolic blood pressure curve was the most reliable. A rise of not more than 20 mm. of mercury indicated an energetic and favorable response provided there were no indications of overtaking the heart. In regard to exercise for patients convalescent from heart failure, they should have no exercise other than sitting up in bed until the temperature had been normal for two weeks. The exercise was then limited to the heart's capacity and the limit of tolerance should not be approached. The exercise should be of such a kind that it could be prescribed in definite amounts. Exercise for cardiac patients was of two types, the energetic type and the mild. Of these the energetic type was the more important. In the milder grades of heart affections where the energetic types were used fatigue and overtaking must be avoided, though in his experience one or two overtakings had not led to any untoward results. The mild forms of exercise were those which stimulated over a long period of time and was suited to patients with a low cardiac reserve. Walking was perhaps the best mild exercise. The patient could begin by walking a very short distance and then resting. As progress was made croquet and setting up exercises might be added. The importance of exercise as a therapeutic agent lay in the fact that it is increasing the power of the heart to withstand or overcome infection and improved the general condition of the patient. Exercise was one of the most important therapeutic agents against heart failure that we possessed.

Dr. ALEXANDER LAMBERT of New York expressed the opinion that this paper was very timely. Three points were worthy of emphasis: 1. That it was the infections of the body that poisoned the heart and not ordinary exercise and exertion of men in ordinary active life. 2. The necessity for keeping the patient in a quiescent state during the period of active infection, which was a most important factor in avoiding heart failure. 3. The value of keeping the heart after an infection within its ability to act, and its improvement when so treated. He did not believe that it was yet accepted, judging from discussions to which he had listened, that septic infections were liable to injure the heart muscles and lead to all sorts of heart involvements. There was no doubt, and Mackenzie and Da Costa had emphasized the fact, that a small passing injury might seriously damage the heart. As to how long a cardiac patient should be kept in bed after rheumatic fever, he should be kept in bed as long as the temperature showed any rise. A temperature between 99° and 100° F. showed a still active process in the heart muscle. As to the value of exercise, when properly used, there was no doubt. Dr. Lambert related that he had been asked to stop and listen to the hearts of the bicycle riders after the week's race in Madison Square Garden, after the men had been riding for four or five days, riding three hours and resting three hours. Those hearts were extraordinarily quiet; they were all about 4½ to 4¾ inches out from the mid-sternal line. The pulse was not higher than 80 in any instance; in one man it was 76; in most of them it was in the sixties. The heart sounds were very faint, the pulse full and strong. The cardiac sounds were particularly lacking in amount. One had a reduplicated first sound and one a reduplicated second sound, but they were intensely pure and going on well within the physiological limit; the sounds were those of a heart with myocardial degeneration. One had to judge by the patient each time as to the possible value of exercise. The value of exercise lay in making the organ increase its health by increasing its function. Exercise trained the heart to better and more easy contraction.

Dr. MILTON H. FUSSELL of Philadelphia said that Dr. Barringer's paper emphasized not only the necessity of the normal individual keeping up a certain amount of exercise during life, but that one could keep up a patient with cardiac disturbance by properly regulated exercise, but he feared we might be over-impressed by the value of exercise and forget the impor-

tance of complete rest after infection. Certainly a safe rule was that an individual with an infection of the heart must remain quietly in bed until the temperature had remained normal fourteen to twenty-one days and then exercise must be taken very tentatively. The patient must first be observed before trying any exercise to see if there was any undue acceleration of the pulse on sitting or standing up in order to be sure that he was not taking exercise too soon.

Dr. ROBERT H. BABCOCK of Chicago said that many points had been so excellently said that it seemed a work of supererogation to attempt to add to what had been said, but he wanted to emphasize the necessity for prolonged rest after acute infection of the myocardium or endocardium. Most physicians were apt to allow the patient to get up too soon, partly because they thought the process had ceased when the temperature came down and partly because it was difficult to keep the patient in bed and to make the family see the necessity of it. Exercise was of great value to many damaged hearts. It might be remembered that the great Stokes insisted on the aortic cases exercising in order to develop hypertrophy of the left ventricle. He allowed the patient to take any form of exercise that did not produce distress, but he rarely allowed the patient to do much swimming. He regarded swimming as dangerous because just as soon as the patient became chilled and cyanosis appeared there was capillary paresis and when capillary paresis took place the heart muscle was subjected to great strain. Exercise was of great benefit not only in stimulating nutrition but the improvement of the coronary circulation called into effect those accessory factors that kept up the circulation and improved the venous return in the course of deeper respiration and muscle contraction.

Dr. GREENE of Boston thought the time for keeping the rheumatic cardiac in bed could not be decided by his temperature but should be influenced by the symptoms during the febrile attack. A patient who had had a mild febrile attack lasting only a few days and a questionable heart murmur—a so-called mitral regurgitation—might be allowed out of bed sooner than one who had had severe symptoms.

Dr. PHILIP MARVEL of Atlantic City asked whether the diastolic pressure after exercise was taken and if so whether it was variable.

Dr. CARROLL E. EDSON of Denver, Colo., feared that in our enthusiasm for exercise in heart disease we might not be discriminating enough in all cases as to what the fundamental trouble was. It made great difference whether a patient had a myocarditis which was toxic and simply needed time enough for a natural restoration or whether he had an infective endocarditis in which, though the heart was quiet and the temperature normal, over exertion might light up a latent infection. It was important to decide whether the heart trouble was due to the condition of the muscular system as a whole or to a senile heart, whether the patient was old in years or not, for one was not going to help that heart by calling upon it for increased exertion. Unless one discriminated carefully he was going to get into trouble in applying exercise to cardiac cases.

Dr. SMITH of New York expressed the opinion that the influence of the Association should go out in favor of physical training in the public schools. A thorough physical examination should of course precede the teaching of physical training. He said he mentioned this matter because a bill to abolish physical training in the public schools was brought before the Legislature of New York State during the last year. His daughter had been instrumental in having that bill amended to read that all schools having over twenty teachers should have a specially trained physical training instructor, while in all schools having under twenty teachers physical training might be left to the regular teachers. Now the regular teachers were not trained, and he felt that the Association should let its influence go but as opposed to the teaching of physical training by those who were not trained and should encourage the employment of a special teacher of physical training in all towns and insist upon physical examination of all children taking the training. He thought they should not encourage excessive training in athletics but that every doctor should be interested in physical training of a kind that would be beneficial.

Dr. BARRINGER, in closing the discussion, said that the discussion had shown that the profession was distinctly alive to the lack of handling of cardiac cases in the past. They had all seen cases of valvular and muscular heart disease come back time and time again and apparently not much progress had been made in their treatment of cardiac cases in the last fifty years. The incidence and the mortality from heart disease was increasing. As to the suitable cases for treatment by graduated exercise, there were the angina cases at which they had all looked askance. Most of these were ambulatory cases; for them it was dangerous to prescribe any but the simplest exercises. They had eliminated the cases of coronary disease. Regarding the cases suffering from recurrent endocarditis or heart failure, which some regarded as the same disease practically, in giving exercise one must be guided by the case. For instance, if one had a child in bed three months with myocarditis, when the temperature had remained at 99° F. for three days the child might be allowed to sit up one hour, then two hours, then he might be allowed to walk around the bed, then fifteen or twenty feet, the amount of exercise being determined by the circulatory reactions, and he should cease if there were signs that the heart was overtaxed. The cases of cardiac failure, whether from muscular or valvular disease, must be treated differently. The patient who was short of breath and his exercise tolerance decreased and who showed temperature up to 100 for four or five days was treated with digitalis and when his temperature became normal might be treated rather early by means of graduated exercise. With regard to the age of the patient, young people undoubtedly had a better exercise tolerance than older ones—those 60 or 70 years of age who might have senile myocardial degeneration; the latter, however, were much more improved by exercise than by being kept in bed, in his experience. Our conceptions of heart disease, regarding its etiology, pathology, physiology, and treatment, were going through a transition and there was going to be a great deal of discussion and experiment before any new ideas were adopted, but he felt the incidence of cardiac failure would be lessened provided attention were given to exercise and to the removal of foci of infection. The truth of that assertion only time would bring out, but he had had enough experience to believe it pointed the road we must travel if we were going to improve our treatment of heart disease which was most lamentably deficient at this time.

Intermittent Hydrarthrosis.—Dr. WALTER L. BIERING of Des Moines, Iowa, presented this paper, in which he stated that he had reviewed the literature on this subject and had found 76 cases of intermittent hydrarthrosis recorded. It was but natural that malaria should have been considered as an etiological factor by some; others maintained that it was a phase of other arthritic lesions, and there was a strong tendency on the part of some to regard it as a vasomotor disorder. The patient reported in the present communication came under observation in 1916. He had passed through the usual diseases of childhood, and gave a history of malaria, rheumatic arthritis and typhoid fever. He first noticed occasional painful swelling of the left knee in the spring of 1909. He became impressed with a certain periodicity of the swellings but kept no records of them. He finally kept a record of them and found that they recurred in cycles of six days at an interval of twelve days. During the interval between attacks the knee appeared normal. No form of therapy had influenced the attacks. The right knee then became involved, the cycle being five days and the interval eleven days. The x-ray examination was negative in both instances. The general examination showed nothing insignificant. The Wassermann reaction was negative, the urine normal; the basal metabolism had never been high. The tonsils were removed after which frequent attacks of suppurative tonsillitis ceased. A devitalized tooth was removed and an operation for hemorrhoids was performed. He had had many forms of treatment including iodine injections, elastic supports, arsenic, quinine, and the iodides, without benefit. The periodicity had now lasted for five years. The uniformity of the clinical symptoms had been noted by all observers which had estab-

lished these symptoms as a definite entity, but so far as the etiology was concerned there was not the same uniformity of opinion. The records of reported cases showed one or both knee joints involved in every case recorded. A periodicity of twelve days prevailed in most cases. The general health of many of the patients was apparently normal. Pregnancy seemed to bring about a remission of symptoms. It occurred in those decades of life in which stress was greatest. In regard to the pathogenesis, the tendency to recur periodically was in accord with the vital phenomena of pathogenic organisms. Bacteriological investigations had been unsuccessful probably because of the tendency for bacterial to localize in the tissues rather than in the fluid in the joint. In none of the cases did the condition seem to be associated with trauma. While there was much in the condition suggestive of a bacterial origin the true etiology remained to be explained. These were also those who tried to explain it as a vasomotor disorder akin to the psychoneurotic functional disorders.

Dr. RALPH KEMPerton of Philadelphia said he was not familiar with the detailed history of the case, but there was always room for such clinical observations. The more one saw of arthritis and the more he studied it the more he felt that the various phenomena tended to be referable to a single basis rather than to different factors. In our classifications of arthritis we had been over-clinical and under-pathological. It seemed to him that this condition was really a part of the picture of the arthritic syndrome at large. The periodicity was difficult to account for; but the periodicity was possibly overemphasized. It was interesting to note that of the sites most involved in over 400 cases studied by them the knee was the most frequent. He had sometimes suspected that effusion was compensatory. He had been interested in the respiratory function of the blood and had come across a rather interesting observation. Whether the arthritis was acute or chronic there was a distinct departure from the percentage of saturation of the blood with oxygen. There seemed to be no real chemical change in the blood but a high percentage of oxygen saturation not referable to the circulatory mechanism. With improvement in the condition there was a drop in the oxygen saturation which they had not come across with the same frequency in other conditions. With regard to the effect of quinine in hydoarthrosis it might be recalled that quinine was regarded by some as of value in arthritis, and it might have some value in reference to oxygen saturation. The chief point to be emphasized was that Dr. Biering's suggestion as to a possibility of the circulatory mechanism being involved in the etiology seemed to have some corroboration.

Dr. E. C. ROSENOW of Rochester, Minn., referred to his experimental work that seemed to show the selective action of certain microorganisms, particularly streptococci, when injected into animals intravenously. In acute arthritic rheumatism the localization was multiple and non-suppurative; the organisms tended to locate in the heart muscle and pericardium and to give reactions characteristic of rheumatic arthritis. In their study of the different types of arthritis it was shown that different strains of organisms showed different selectivity in their localizations. With some strains there would be marked exostoses and there was usually suppurative lesion in the joint; in others this did not occur and the lesion was periarticular. In regard to localization in the knee joint, the knee joint in animals as in man was particularly liable to insult. A point which might account for the circulatory disturbances was that in most chronic forms of arthritis the organism did not have the power to locate in the joint but located around the joint and in the tendons around the joint so that the lesion was associated with endothelial proliferation and cut off the vascular structures, interfering with the growth of the organisms but producing lesions somewhat similar to those produced by the living microbes.

Dr. JOSEPH ROSENTHAL of Brooklyn asked as to the incidence of heart involvements in this series, and whether there were any blood changes during the attacks, particularly with reference to the lymphocytes. He also asked with reference to the tuberculous history in these cases.

Dr. BIERING, in closing the discussion, said that in reference to the blood examination, at no time was there a leucocytosis and at no time a disproportionate increase in the lymphocytes. The coagulability of the blood was normal. There was no abnormality in the sugar or other blood elements. There was no instance of tuberculosis in the history of the patient or his environment. With reference to the blood changes, Barker had called attention to a change in coagulability, but this had not been corroborated by other observers. However, that there might be blood changes was quite possible. He recognized the tendency to associate this peculiar swelling with arthritis particularly because it was connected with arthritis in the beginning. There were in most of the cases no other symptoms of arthritis. Because of the peculiar circulatory supply, to which Dr. Rosenow had called attention, there was a close association with the nervous system and a close association with the joint and one could appreciate that a low grade organism might locate there and the reaction would not correspond to the usual response to an infective organism but might simply lead to a transudate and might also account for the periodicity, it taking a certain time for the fluid to accumulate and to disappear.

The Acute Element in Chronic Nephropathies.—Dr. CHARLES P. EMERSON of Indianapolis read this paper in which he asserted that two processes were usually associated in the production of a chronic nephropathy; the acute injurious element, the infection, intoxication, tissue starvation, etc., and the process of tissue repair. The tendency of the injured kidney was always toward recovery. If, therefore, a neuropathy continued unimproved it was not because of the initial lesion, but because the injurious factor continued to inflict new injuries. That meant that chronic nephropathies consisted of a succession of slight attacks of acute nephritis, each adding its injury to the kidney. As evidence of the acute process, we had often a slight fever and an inflammatory exudate of albumin, casts, and various cells in the urine. In the intermissions between these acute attacks the urine might become quite clear, although the kidney might have become greatly injured. During the intermissions the permanent injury might be evaluated by renal test meals, the functional renal test, etc., but during the acute attack these dominated the picture.

Dr. CHANNING FROTHINGHAM, JR., of Boston said that testing the nitrogen and the albumin during the intermissions in nephritis in the way Dr. Emerson had described would be a distinct advance. He could not help wondering whether this increase in nitrogen meant any actual fresh injury to the kidney, but he had been impressed by the difficulty of making up ones mind from a study of the urine as to what was going on in the kidney. There were no tests that allowed one to decide what type of kidney disease was going on. Our inability to determine the type of pathology from the clinical symptoms was to be regretted because it made a difference in handling a case. Some lesions would heal up without leaving permanent scars and some left permanent lesions.

Dr. E. C. ROSENOW of Rochester, Minn., spoke of experiments which he had conducted that had a direct bearing on diseases of the kidney. During a course of experiments with various microorganisms, streptococcus chiefly, these organisms were successively passed through animals and it was found that as they were brought from a low virulence there was a certain point where localized focal lesions in the kidney were the result. In a series of cases of kidney lesions, not many, some chronic, others acute were produced by the intravenous injections from foci of infection such as the tonsils and the teeth. The organisms from seemingly harmless foci in this series of experiments showed a tendency to localize in the kidney. The type of lesion was such that it made one think very strongly that it might be the cause of exacerbations of the kidney disease. In their experimental work the interesting fact that the kidney had great recuperative powers had been noted. The tendency to exacerbations in the chronic forms of nephritis strongly indicated that there was a foci of infection somewhere in the body which was feeding the kidney process. They had recently infected the pulp chamber of devitalized teeth in

dogs with organisms having the power to localize in the kidney when injected intravenously. The results seemed to show that the continuous feeding in of small amounts of an organism having a tendency to localize in the kidney would result in pronounced and advanced lesions of nephritis.

Dr. EMERSON, in closing the discussion, urged active treatment of the original acute attack of nephritis with removal of the foci of infection and emphasized the importance of looking out for the little flare-ups which were evidenced by a rise of a half or one degree in temperature and an increase in the albumin and nitrogen.

SECTION ON DISEASES OF CHILDREN.

First Day—Wednesday, June 8.

Dr. FRANK C. NEFF of KANSAS CITY in the CHAIR.

Chairman's Address: The Section on Diseases of Children.—Dr. FRANK C. NEFF of Kansas City delivered this address, in which he urged that an effort be made to create a complete roster of the membership of the section so that its work might be made available to all those interested in questions pertaining to children. At present only a limited number of the papers read before the section could be published in the official Journal and thus many valuable papers were lost to the members which might reach them if they were enrolled with the section; all those thus enrolled would receive reprints of papers read before the section. Such a list of the members of the section would enable the officers of the section to gain more information as to the work being done throughout the country which would make it possible to provide more interesting programs and to avoid the repetition of subjects unless some definite progress had been made in those particular lines. Papers should be sent to the section officers at least three months before the time of the annual meeting. This would permit the officers to make a selection and the papers returned could sometimes be presented at a future meeting. Guests from foreign countries interested in child welfare work and diseases of children should be invited to contribute to the program. There were now many young men capable of doing research work who had too little time and money to permit of their following such lines of work. In order to give such men an opportunity for doing research work that would be of value to the pediatrician and to the profession at large Dr. Neff said there was a project under consideration of establishing a fund to be known as the Abraham Jacobi pediatric fund. It was proposed that subscriptions to this fund be voluntary and that an executive secretary should be custodian of the fund. This fund should also be used for the publication and dissemination of reprints of the proceedings of the section.

The Relation of Posture to the Health of the Child.—Dr. FRANK DICKSON of Kansas City, Mo., read this paper in which he said that good health was necessary for the proper development of the individual. The physically unfit child was the backward one mentally. Any factor which limited or prevented the child from engaging in normal activities was a menace to health. A child might conform well to the standards of height and weight and yet fall below normal as regards health. Dr. Goldthwaite said that to stand erect and move with ease was desirable for very much more important reasons than those purely esthetic, namely, that one might use the body with less expenditure of energy and with greater efficiency. A considerable proportion of the large number of our young men who were found unfit for military service was so because of defects due to bad posture. The correct posture of chest up, abdomen in, and feet straightforward furnished the conditions for the greatest activity with the least expenditure of energy. The opposite posture, sunken chest, protruding abdomen and flat feet was conducive to muscle fatigue. A large proportion of children had a sufficiently bad posture to cause symptoms. Dr. Dickson quoted statistics to show that postural defects were sufficiently frequent among children to demand attention. The present paper was based on 48 cases, ranging from 1½ to 14 years in age. Postural defects might be divided into congenital and

acquired. The congenital type were those with lax muscles loose joints and a tendency to enteroposis—the long slender type of child with lordosis and round shoulders. In the acquired type there was an increased accentuation of a tendency to lordosis and prominence of the abdomen, the feet were pronated; in a word, the body was out of balance, which necessitated a readjustment so that the center of gravity might support the body. Of the 48 cases studied in this series 12 were the result of congenital conformation; in 21 cases rickets was present; in 5 the glands of internal secretion seemed to be at fault; in 5 syphilis was the cause of the defect. The muscle fatigue resulting from bad posture expressed itself in such symptoms as legache, kneeache, backache, restlessness, irritability, and in older children in lack of concentration and failure to get on in school. A considerable number of children having these deformities acquired them as the result of rickets. The long slender type of child with a ptosed stomach which failed to empty itself normally and dragged on the duodenum and gall bladder was liable to suffer from recurrent attacks of gastrointestinal upsets. These attacks frequently occurred about once a month. Talbot and Brown had explained that bad posture might explain cyclic vomiting together with a certain degree of fat intolerance. Functional albuminuria was often seen in these cases. Arthritis was occasionally seen associated with poor posture. Dr. Dickson said he did not claim that all symptoms from which these children suffered were due to bad posture alone, but the presence of one or more of these symptoms suggested that a consideration of the body posture was indicated. The treatment of these children consisted in training in proper postural habits, regulation of the diet, correction of deformities and exercise, each of which was equally important. In conclusion it was suggested that bad posture might even furnish the explanation of some acute conditions, hence a careful examination of every child in reference to body mechanics was of importance. In the handling of these cases there should be cooperation between the pediatricist and the orthopedic surgeon. Attention to posture was important because of its effect on the later life of the child.

Dr. BORDEN S. VEEDER of St. Louis stated that for a number of years he had taken considerable interest in a group of underweight and thin children with no striking pathological condition, most of them coming from homes of good economic circumstances so that lack of proper food seemed not to be the cause of the malnutrition. For a time he was inclined to attribute the condition to heredity, characteristic traits or something of that kind. But he found that this did not seem to furnish the explanation of the condition. He observed two or three of these cases in the home and it seemed that the basis of the condition lay in fatigue and treatment based on that theory had given prompt results. If one watched these children it was found that they became tired in their play, and forgot to relax. The causes of fatigue might be multiple; it might be due to bad posture, to overwork or overplay or overstudy. The complex lives of many modern children, too many parties, too many movies, too much excitement, and too little rest and relaxation might be found the explanation of the condition presented by these children who were simply under weight and under par and in whom there was no definite pathologic condition. The removal of physical defects was not the entire solution of the problem of handling these children; one must study the environment in which the child was living and among other things see that he was getting the amount of sleep he required. Published statements in regard to the amount of sleep needed by the growing child were very indefinite. These had been analyzed and a record of sleep in a group of malnourished children had been made in an attempt to determine the importance of this factor. The amount of sleep required was an individual matter but there was a minimum of sleep which every child must have. Such a minimum he had worked out. It was as follows: A child of 1 to 2 years required 13 hours sleep in twenty-four hours; one 2 to 4 years of age required 12 hours; from 4 to 6, 11 hours; from 6 to 10, 10 hours, and from 10 to 14, 9 hours. It must be remembered that this was only a minimum to be used as a basis for judging

of the amount of sleep necessary for each individual child. In order to ascertain how great a part insufficient sleep played in malnutrition, Dr. Veeder studied a series of 80 children, 15 to 20 per cent. of whom were underweight, checking up the number of hours of sleep they were getting. He found that 40 per cent. of these children fell below the minimum requirement as regards sleep. Then, too, the conditions under which they slept played a part, such as whether there were one or two in a room, two in a bed, the size and ventilation of the room, etc.

In closing, Dr. Veeder said that the more he had studied this matter the more he had been impressed with the importance of rest and relaxation in relation to the general health of the child and the problems of malnutrition. Propaganda directing attention to the need of restricting the activities of these malnourished children was needed as much as that setting forth the need of proper clothing, bathing, care of the teeth, and proper diet. Modern life interfered seriously with the growth and development of a great many children.

Dr. FRITZ B. TALBOT expressed the opinion that these two papers had dealt with two very important factors in the well-being of children. The question of fatigue and the question of good posture so interlinked that they formed a vicious circle; fatigue made poor posture and poor posture made fatigue. When poor posture was corrected the fatigue ceased. It was important to remember that in connection with mechanical devices used in the correction of improper posture. In the reports he and his associates had made on extreme cases of improper posture with extreme symptoms he thought they had shown how important posture could be in severe cases. Dr. Dickson's paper emphasized the same thing in reference to the milder cases. It was a rather common experience for those who were taking posture into consideration to find that when the posture and fatigue were corrected lines under the eyes, lack of appetite, and constipation disappeared and efficiency increased. Dr. Talbot emphasized the point that in cyclic vomiting one must always bear in mind that he was dealing with a potential appendicitis. One must always remember that the underlying basis of cyclic vomiting might be not posture but chronic appendicitis. That had been the after history of two cases that improved when the posture was corrected but did not become entirely well, so one should not be carried away by enthusiasm in the correction of posture defects and forget that there might be a surgical condition back of it. However, the results of correction of postural defects were sometimes brilliant.

Dr. C. F. WAHRER, Fort Madison, Iowa, brought out the point that many of these children had malposition and malnutrition because they were constitutionally inferior. If one looked at the parents of these children he would see that the parents had these same defects and that we had to break in on a vicious circle. The parents must be taught that they must not permit such positions in their children. The family physician must draw attention to this matter and the poor school teacher who had been made responsible for everything must be asked to help and a paternalistic government must take a hand. The matter of posture was indeed no small thing. A proper carriage was an important matter in the self-respect of the individual, aside from any question of pulchritude. Perhaps when the family physician brought the matter of posture to the attention of the parent he would be told that it was none of his business but he should not be disconcerted by that but should be proud to be the instrument in making a better, a greater and a prouder mankind.

Dr. JOHN A. FOOTE of Washington, D. C., said that Dr. Dickson had made the statement that deformities or mechanical defects produced malnutrition, he thought it important to mention that malnutrition produced mechanical defects, and while it was proper to say that these conditions were due to muscle strain and maladjustment in the acquired types we did not know as much as we should know. Dr. Schroeder of New York, who was doing work of this kind for the Association for Improving the Condition of the Poor, had investigated some 2,000 children and her observations according to age grouping were worthy of attention. She found in the children from two to six years of age, the pre-school group, a very startling number

of orthopedic defects. The orthopedic defects ranged between two and three per cent. in all the children of all ages, while in the children between the ages of two and six years 24 per cent. showed orthopedic defects. In the children from six to twelve years there was a drop to less than eight per cent. Further analyses of the observations made in this series of children showed these defects to be due to deformities of the long bones and deformities of the thorax and bony spine. It would seem that in a study of this kind one could find some of the reasons for muscle fatigue. The posture habits were formed in childhood when the child was trying to correct defects of the long bones and in that way he acquired certain habits of muscle imbalance which persisted after the original orthopedic defects were cured. In the prevention of rickets we had a means for the prevention of orthopedic defects, and this could be done by encouraging maternal feeding and providing a suitable diet to children.

Dr. C. H. JOHNSTON of Grand Rapids said the books stated that poverty, malnutrition and tuberculosis went hand in hand, and he did not have statistical data to deny that statement, yet the observation of a large number of malnourished children showed that this condition was more common among the children of the rich than among those of the poor. In a district inhabited by the rich 40 per cent. of the children were found to be malnourished, while in a poor district only from 20 to 25 per cent. of the children were found to be suffering from malnutrition. He thought they were going to find that there was some other cause of malnutrition in children besides poverty and tuberculosis. Next year he would like to have someone read a paper showing the specific part malnutrition played as a cause of tuberculosis.

Dr. E. J. HEUNEKENS of Minneapolis, Minn., emphasized what had been said in reference to malnutrition as a cause of bad posture and as to the benefit of rest in malnutrition in children. After listening to the paper of Dr. Talbot and Dr. Brown last year, Dr. Heunekens said he spent two weeks in Dr. Goldthwaite's clinic and then went home and applied what he had learned in his clinic for pre-school children. The first thing was to get the child started in the Goldthwaite position and then much could be done by systematic exercise to develop that position. When the physical defects were corrected it was found that there was faulty diet and faulty home environment in at least a large proportion of the cases. In a fairly large number of cases there was a neurotic atmosphere and treatment had to be directed to the parents.

Dr. DICKSON, in closing the discussion, said he did not intend to convey the impression that he thought postural defects explained all the things they had found in this series of cases. There were other elements. Of the 48 cases 21 showed evidence of rickets. For that reason he never consented to handle one of these cases unless he had a pediatricist with him, because it was only by the close cooperation of the pediatricist and the orthopedist that the best results could be obtained. Those in orthopedic work were in a little better position to correct postural defects than the orthopedist and he was sure that when it came to regulating the diet the pediatricist could do better than the orthopedist. He thought they should get together and train the children and give them a fair start in life.

Dr. S. BORDEN VEEDER of St. Louis said that they all recognized that malnutrition was a complicated subject. Up until last year in their work all the attention had been directed to diet and the correction of physical defects, such as carious teeth and bad tonsils, but it had been his experience that these things would not cure a large percentage of cases and hence he wished to emphasize the importance of rest.

(To be continued.)

Syphilis and Diabetes.—Pinard and Violnet in 1,000 miscellaneous cases found twenty-three with glycosuria or diabetes, and of this number fifteen had contracted syphilis, or were heredo-syphilitics. This frequency of a syphilitic factor will explain certain symptoms common in diabetes, as areflexia, ocular paralyses, and monoplegias.—*Gazette des Hôpitaux*.

Books Received.

The MEDICAL RECORD is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.

INFEKTION UND IMMUNITÄT. Von M. LOEWIT, M.D. 550 pages with illustrations. Published by Urban & Schwarzenberg, Berlin and Vienna.

EDEMA AND NEPHRITIS. By MARTIN H. FISCHER, M.D. 922 pages with illustrations. Published by John Wiley & Sons, Inc., New York.

TRANSACTIONS OF THE AMERICAN SURGICAL ASSOCIATION. Volume 38. Edited by J. P. JOPSON, M.D. 709 pages with illustrations. For sale by Wm. J. Dornan, Philadelphia.

THE EARLY STAGES OF TABANIDÆ (Horseflies). By WERNER MARCHAND, M.D. 203 pages with illustrations. Published by the Rockefeller Institute for Medical Research, New York.

DISEASES OF THE SKIN. By J. M. MACLEOD, M.D. 1307 pages with illustrations. Published by Paul B. Hoeber, New York.

COMPLETE INDEX TO KEEN'S SURGERY. Volumes I to VIII. 182 pages. Published by W. B. Saunders Company, Philadelphia.

PRACTICAL CHEMICAL ANALYSIS OF BLOOD. By VICTOR CARYL MYERS, M.D. 121 pages with illustrations. Published by C. V. Mosby Co., St. Louis.

SURGERY, ITS PRINCIPLES AND PRACTICE. Edited by WILLIAM WILLIAMS KEEN, M.D. Two supplementary volumes. Published by W. B. Saunders Co., Philadelphia.

NEW BOOKS AND OLD.

VIII. PUSCHMANN'S HISTORY OF MEDICAL EDUCATION.

BY JOHN RUHRÄH, M.D.,

BALTIMORE, MD.

EVERY medical library should possess a copy of this work, either in the original or for the benefit and comfort of the American students, in the English translation of Evan H. Hare. This is not a new work, and the translation dates back thirty years, but it is an extremely interesting series of essays of considerable length, dealing with the progress of medical science. It is not only a history of medical education, but a history of medicine as well. The earlier ages are dealt with very much more fully and very much more entertainingly than the later periods, and the consideration of medical education as it was at the time the book was written is very sketchy and well worth amplification. But Puschmann did his work well, and the volume is a tribute to his interest in the history of medicine and of his understanding of it.

He begins far back in the beginnings of civilization in the East and from the days when Charaka and Susruta composed the Ayur-Veda. Charaka's name is connected with the study of the history of medicine in this country, as the New York organization devoted to this purpose bears his name. Among his other recommendations was the intercourse with other doctors.

For conversation with a colleague increases knowledge, confers pleasure, enlarges experience, imparts readiness of speech, and induces consideration. Whoever is uncertain about something learnt, will have his doubts removed by repeated instruction; whoever has no uncertainty or doubt, will be able to fortify his opinion. Thus often a man comes to hear what up to that time he never knew. Often a teacher can seize the opportunity of a conversation of this kind to fully and at once impart to his pupil some information partially or entirely withheld hitherto.

Susruta outlined the requirements that a man should possess before choosing the profession of medicine. Among other things he remarks that he should be sixteen years of age, should show a respectable behavior, should possess a love of cleanliness, kindness, and bodily strength, understanding, a good memory, and the desire to learn and to reach the ends he has in view.

He must have a clean tongue, small lips, regular teeth, a noble countenance, well-formed nose and eyes, a cheerful spirit and good bearing and be prepared to undergo weariness and pain. And whoever possesses the opposite characteristics should not be admitted to the doctor's calling.

The writings of these two old worthies often read like the addresses so often given to medical students on the day of their graduation, showing that we have not gone far in the relation between doctor and patient.

Going Westward, medical teaching in Egypt is briefly touched upon, and one of the passages translated by Chabas is as follows:

Let not idleness overtake thee, else shalt thou be severely chastised. Hang not thine affections upon pleasures and take care that the books fall not from thy hand. Exercise thyself in conversation and speak with thy superiors in learning. When thou shalt grow older thou wilt recognize how important this is: whose is dextrous in his craft achieves power and fame.

As Puschmann states, the medical student of those days was not unlike those of ours. Up to the date of the great drouth, you find one of the teachers reproving a pupil in the following quotation taken from Lauth:

It has been reported to me that thou neglectest thy studies and seekest only thy pleasure, wandering from tavern to tavern. But what profiteth the odour of beer? Avoid it; for it drives people away from thee, impoverishes thy wits, and likens thee to a broken oar upon the deck of a ship.

Medicine among the Jews, among the Parsees, in Greece before Hippocrates, and later during his era receive due attention. The Roman teachers are pictured in a satisfactory manner, and the tricks of the trade to which the profession of medicine often descended are commented upon sufficiently to permit us to learn that quackery is no new thing. His account of Soranus does not seem to me to give one of the greatest of the ancient physicians his due meed of praise. The author goes on with a discussion of the influence of Christianity on medicine, then passes again to the East to comment on the Arabian civilization and upon medical science among the Arabs.

One is surprised at the size and importance of the hospitals of this time, which in many cases served as institutions of medical teaching. After the medical rounds the students seated themselves on carpets in the courtyard and were lectured often for many hours by the various professors. Such were the hospitals at Ray, the birthplace of Rhazes, at Ispahan, and Damascus. Perhaps the most remarkable of all was the great Mansurian hospital at Cairo, built by the Sultan, whose name it bears. He took the residence of one of the princesses, tore it down, and used the material to rebuild. All the skilled workers of Misr and Cairo were made to work steadily upon it until its completion, and the Sultan himself visited the hospital daily until it was completed. Fortune favored him, for in making the excavation a box filled with gold and precious stones was found, which paid for the cost of construction. The hospital served as a center of some other activities, as a mosque in which the Koran was constantly read, and there was also a library for the medical students which was under the care of six eunuchs.

Among the wise teachers among the Arabs was the Jew, Isaac Israel, reputed to be the author of "The Doctors' Guide." Puschmann makes several quotations from it, which have been subsequently used a great deal, and doubtless old Isaac got them from someone else.

The most important problem for the doctor is, how to avert illness.

The majority of diseases are cured by the help of Nature without the aid of the doctor.

If you can cure the patient by dietetic means, forbear to order drugs.

Never rely upon magic in the treatment of a patient, since they mostly rest on folly and superstition.

Hold forth the prospect of recovery to patients, even when you are not assured of it yourself; so shall you at least second the efforts of Nature to cure them.

If a doctor has come from afar, and speaks a foreign language, then the multitude think him a clever man, come to him in crowds, and seek his advice.

Never speak unfavourably of other doctors; for everyone has his successful and his unsuccessful

times. Let your deeds speak your praises, not your tongue.

Visit your patient when he is at his worst. At that time come to an understanding with him about your fee; for if the patient is well he takes no thought of the matter.

Make your fee as high as possible, for what is done gratis is considered of little value.

Bestow the greatest attention upon the cure of princes and rich people; for after their recovery they will be munificent to you, will always value and love you, whereas common people when they are cured hate you if they think of the fee.

Puschmann passes rapidly along to the teaching of medicine among the Germans and in the monastic schools. That specialization is no new thing is evidenced by some of the early writings. Thus in Alcuin's poem on Charlemagne, "One let the patient's blood, another mixed herbs in a pot, that one cooked some pap, while this one prepared a drink." The school of Salerno, of which I hope to write more fully at a subsequent time, comes in for an interesting chapter, as does, also, the medical school at Montpellier. One would like to linger longer over this and over the ancient academies of Italy and France, and the other universities of Europe.

The teaching of anatomy, of medicine, and pharmacy are detailed at some length, as are also surgery and midwifery. One of the most fascinating is the account of medical examinations, and the various titles. One reads with joy a few paragraphs and laughs in his sleeve, when we consider the growing tendency of American physicians to add a string of letters after their names. Listen to Puschmann:

When people began to distinguish between the Doctores legentes et non legentes,—between those who made a practice of teaching and those who neglected to do so—the custom arose of calling the former Professors.

This expression also draws its origin from the ancient times; it comes from Proflteri "to practice or teach publicly an art or science." At the German universities the title "Professor" came first into vogue in the 16th century and only those academical teachers were designated by it who were commissioned to hold lectures and for the instruction they imparted in this way drew a salary or remuneration. They were in fact members of the College of Teachers, called, at an earlier time, Doctores legentes.

The change in the significance of titles and forms of politeness, which is effected in course of time, has its foundation for the most part in human vanity. At the present time it is the case with the title of Professor as it formerly was with that of Doctor; it is bestowed on members of the medical profession who hold themselves quite aloof from the function of teaching whereas many academic teachers are already less inclined to bear the title of Professor than such titles as Geheimrath, Hofrath, or Regierungsrath.

Further I cannot go, but I hope I have given a sufficient account of this book to make whoever reads this wish to possess it, and they will not go wrong if they are fortunate enough to pick up a copy.

Theodor Puschmann began a "Handbuch der Geschichte der Medizin" which was subsequently completed by Pagel and Max Neuburger. His name will go down in the history of medicine perhaps for a long time, inasmuch as his widow endowed the Institut für Geschichte der Medizin, at Leipzig, in 1909, by leaving an endowment of five hundred thousand marks. The admirable work of Sudhoff, the director, I hope to comment on at some future time.

Visit of Edinburgh Students to Paris.—Recently a body of seventeen students from the University of Edinburgh sojourned a month in Paris for the purpose of attending the obstetrical clinics of the metropolis. At a reunion which they attended the Dean of the Medical School, Professor Roger, made an address of welcome during which he dwelt on the ancient friendship of France and Scotland. It was more than a friendship, for the two races sprang in part from a common stock. The same megalithic monuments occur in both countries. The trip was the result of a conference between the Dean of the Faculty of Edinburgh University and Professor Bar, the senior obstetrician of the Paris Faculty. The courses were conducted by Bar, Brindeau, Couvelaire, Faure, and Lequeux. The visiting students were quickly formed into three classes to be assigned respectively to the Baudelaire and Tarnier clinics and the clinic of the La Pitié Hospital. The latter, as is well known, is used particularly for the instruction of midwives. The instruction was conducted in the English language. The movement is not the first post bellum attempt at medical rapprochement, for Spanish students have been receiving instruction for some time in their own tongue in various metropolitan clinics. It is not denied that these adventures are a part of a system of French propaganda. France does not propose to be caught napping by the Teutons again, and will see to it that her good things receive the best sort of publicity.

Evolution of Modern Diagnosis in France.—In an inaugural lecture to his faculty course on internal pathology reported in *La Presse Médicale*, April 30, 1921, xxix, 35, Professor Renon briefly sums up this subject. Some of the older authorities had some knowledge of physical diagnosis, for we find mention of auscultation in Ambroise Paré and of percussion in Tagault. But the new science practically dates from 1803 when Corvisart translated the work of Avenbrugger on immediate percussion. In 1823 Piorry introduced mediate percussion and in the meantime Laennec, in 1819, had published his treatise on mediate auscultation. In 1841 Gruby was the only expert microscopist in France and among his discoveries was a trypanosome in the blood of a mare. He was so far ahead of his time that nothing further in this direction was done until the time of Davaine, the immediate forerunner of Pasteur. In 1847 Duchenne de Boulogne made his earliest contribution to the art of electrodiagnosis. Some time later came the great revolution incident to the introduction of bacteriology. In 1892 Louis Martin independently differentiated diphtheria from other anginas. Talamon discovered one of the pneumococci, Laveran the *Plasmodium malarie*, etc. In 1896 Widal introduced serodiagnosis and a few years later cytodiagnosis. Marie isolated acromegaly and Babinski discovered his reflexes. Bordet and Gengou introduced diagnosis by complement deviation and Richet the conception of anaphylaxis. Widal has been identified with innovations for more than a quarter century. Among them is the relation between the chlorides and edema, and quite recently the hemoclastic crisis.

THE MORAL CENTER IN THE BRAIN.

(CORTICAL REGION FOR CONTROL OF MORALS)

ITS LOCATION AND SIGNIFICANCE.

By WILLIAM BROWNING, M.D.

BROOKLYN, N. Y.

(Concluded from page 1048)

Analysis of Cases.—In considering these focal brain troubles the custom will be followed of recognizing two classes of symptoms, the general and the special (general and special localization). The present cases are reported for their value on the general side.

Cases of this clinical type are seen now and then at all our large care institutions. State hospitals, reformatories, truant homes, prisons, and the like all prove to be occasional landing places for these unfortunates. But cases that are demonstrative in the present sense are far rarer, and so scattered that no one evidently has seen enough to recognize their bearings.

The cases above related are from a number of known observers. To an unusual degree the personal element of a single reporter is thus excluded. This serves the further purpose of verification of material. Half the cases have also been examined by the writer.

Five of these were in families of means, making the delinquencies all the more flagrant. And all were, so far as determinable, from families of good repute. A history of the immediate relatives was obtained in eight of the cases. Possibly in Case VIII the sexual phase may have been influenced by remote heredity, but, even so, that does not account for the case as a whole.

To imagine that primary unmorals are specially disposed to acquire right frontal injury is too absurd to need argument. Doubly decisive in this regard are Cases V, X, and XI, where a normal changed to a low-grade moral.

As American, English, Irish, Hebrew, Italian, and German are represented, even in this limited number, it is clear that neither race, sect, nor previous condition is a factor. Though these are all Caucasian, no race has a monopoly of virtue, nor is any minus a frontal lobe; each, therefore, can claim a moral center, or potentially "something just as good."

In each of these cases, considering their respective walks in life, a moderate degree of intelligence was preserved; on this score they might all pass as average persons. And three (I, IV, VII) were intellectually well above question.

In three (I, III, VI) there was a history of convulsions for a time, not a chronic epilepsy. It is

not apparent that this affected the relation of either case to the present question.

In two cases the scar extended a trifle across the middle line (VI, VII). But in these there was no evidence of subjacent damage on the other side; at most, it could have been but minimal.

Five of the cases were due to forceps injury at birth. While this speaks for regional accord, it does not prove exact identity of site nor equality in the size of the lesions.

Three of these were in left-handed persons, and in each the injury was in the left instead of the right frontal region.

The evidence in each of these ten cases points to injury chiefly and for the most part exclusively of the recessive (usually the right) frontal lobe. In two (VIII, IX) the external scar may have extended farther back. But as in these two there was no motor involvement, it is certain that the brain injury was forward of the central region. In Case III there was some involvement of the arm center, but more of that for conjugate deviation, situated forward of the arm center. And so long as the damage was limited to the right hemisphere the present contention is not materially affected.

As the damage in each was caused by external violence, and as there was a localizing scar in each (except Case III, in which the clinical evidence was to the same effect), it is certain that in each there was some degree of cortical involvement (as by trauma, pressure, or scar).

Whether shock and contusion effects, short of gross lesion, can disjoint such a center sufficiently to disable it permanently is a question that does not specially concern this discussion.*

What is meant by morals? It is not necessary to discuss old definitions, but only to speak for present purposes. The delinquencies found are of two kinds:

On the positive side: Stealing, forgery, bribery, deceit, reckless greed yet improvidence, extravagance and profligacy, gambling, "pathological lying," obscene language, impersonation (imposter), running away, breaking parole, expulsion from school, vagabondage, runaway marriage, over-excitability, violence actual or implied, instability, drunkenness, hypersexuality, prostitution, bad associates, roguery, cruelty, restlessness.

Recorded observations of others include also, as products in some cases, drug addiction, pyromania, suicide, homicide, "frightful cruelty," "a universal badness," poisoning, swindling, fraud promotion, desperadoes, trickery, borrowing and pawing, cunning, "wayward and self-willed," "tendencies to ex-

*Cf. Specht Sagenannte Naval Insanity nach Gehirnerschütterung, *Med. Klinik*, 1918, xiv.

cesses of all kinds," selfishness, yet a care withal to clothe these acts "skillfully in legality." Gehry (*Correspond. f. Schweiz, Aerzte*, 1913), speaks of a criminal impulse (Trieb). Practically this covers the whole gamut of immorality and criminality.

On the negative side: Loss of the sense of fear, shame, remorse, misgiving, responsibility, duty, obligation, honor, the proprieties, regard for "the feelings and rights of others," lack of normal humane instincts or altruism, "utterly incapable of telling the truth or understanding why they should do so," incorrigible. "The constitutional unmoral is extremely suggestible," yet "These persons apparently learn no lesson from experience." "No sense of the necessity for property rights" (Bolsheviki by nature just as are all mere animals—with apologies to the dog and horse!) They crave excitement, change, adventure, self gratification. "They want gaiety, which leads them into dissipation." "Vice. All its innumerable forms are derived from inordinate self love" (Rush). Not all these acts and sub-moralities hold, of course, against every case.

On the other hand, they are not stingy, tight-fisted, or miserly: are often "very popular" even outside of their pals; show "a cheerful adaptability to the inevitable"; and are sometimes capable spontaneously of a bravery and heedless generosity, a nobility of conduct, to which ordinary mortals are less disposed.

The absence of timidity, fear, and forebodings makes an excellent ground-work for success in criminality. They can be far more successful as criminals than can the upright. Risk, doubt, consequences, chances, possibilities of harm to themselves or others do not arise to unnerve and unsteady. Psychically dare-devils and steeple-chasers must be closely akin.

In none of the above cases do the histories preserve more than illustrative items of the many anti-social acts of the individual. Such a multitude of transgressions have been related, even in less frank cases, that whole articles might be filled if that phase as such were the present topic of study. Suffice it to note that each has been serious enough to require medical or institutional care. Were it only a medical matter it is time to have some principles worked out for both their understanding and management.

While actual personal violence (assaults and attacks on life) is less in evidence in the above cases, it is implied in several. Both logically and by association it belongs in the unmoral picture. Such deeds, however, soon land the doer in prison, and cases from that source have not been secured.

These ten cases then have two large features in common: On the one hand a history and evidence of injury in the right frontal region, of a character that necessarily involved some portion of that frontal lobe; on the other a record of subsequent immoral anti-social and variably criminal acts. That the relation of these two is that of cause and effect hardly needs argument. Details may remain to be determined, but regarding the main questions the evidence seems conclusive.

So far as known, there is no like list of cases involving this or any other limited portion of the brain. Of course anyone of experience has seen occasional cases of excitement, alienation, and even

violence from injury to various parts of the cerebrum. But such cases are not to be confused with the present group; nor are they of sufficient uniformity to have any localizing significance.

As in nearly all principles of cerebral localization a start has to be made with material that is approximate rather than exactly determinative of the location. Instead of post-mortem and histological examinations we are here able to cite injuries, scars and histories as proof of the site of the lesion. A single instance can be easily picked to pieces. But from a series of such cases, to the extent that they show uniformity, approximate localization is warranted and veritable conclusions of value can be reached. For greater exactness of detail it is desirable to have anatomic descriptions of like cases; but this need not prevent the clinician pointing the way. It is hardly a field for animal experimentation. But as the conditions in these cases were all acquired, each represents a human experiment.

Though Broca's work is over 50 years old, there are still queries about the character extent and relation of his conclusions. The present is hardly less incisive. It opens the right hemisphere which has so long been but a puzzling balance wheel. It also indicates that the higher mentality* is responsive to physiologic law.

A Psychic Inhibitory Center.—Next in importance to the facts is the presentation of a working theory for their proper understanding. How is this impairment of morals consummated? In point of fact none of these unmorals is at every instant criminal or even bad in his actions. Much of the time and when under favorable surroundings they act just as morals do. It is only at times and under certain conditions (as excitement, temptation, craving for adventure, sudden impulse, absence of restraint) that anti-social conduct develops. There is consequently no actual loss of any function requiring motor activity for its expression, but only a failure at times to keep such functions within proper bounds.

To follow the matter concretely, two items will be selected (lying and forgery) from the category of their iniquities. As these acts are executed by centers in the left or dominant hemisphere, and as this can be done quite as perfectly after damage to the right frontal lobe, it is certain that the primary source of the impulse thereto does not reside in that lobe, but only the power of controlling or restraining these acts for moral purposes.† This shows the control of morals to be identical with the well-recognized form of nerve-function called inhibition.

The truth of this interpretation is fully corroborated by the character of the unmoral acts. As fear, duty, remorse, etc., are all restraining influences, and consequently inhibitive in character, their loss or impairment means that there has been a corresponding loss of normal inhibition. And in the same manner the unmoral aggressive acts show

*"The moral sense is the highest faculty of man," B. Sachs, in "Legal Medc.," 1894, II, 201.

†The same facts and reasoning make it also clear that these cases do not prove the existence of a sexual center in the right frontal lobe (as might at first be imagined), but only that sexual activities are under the inhibitive control of that lobe.

the loss of inhibitive control. Therefore, all the aberrations can best be attributed to a loss of normal psychic inhibition.*

A point comes up here that is not necessarily involved in this discussion, but is so much related as to have an important bearing. This refers to the source of initiative that starts motor activity. When the motor stimulus originates in the motor center itself, we get only cortical or Jacksonian spasm, *i.e.* non-purposive unmotivated action. Hence per contra all purposive action must originate at some higher point in the cerebral scale. Such higher sources of initiative constitute supermotor or psychic-emissive centers.

From this it is evident that the supermotor centers are functionally of two types, the activating and the inhibitory. In the present instance the two are not only not identical in site but appear to be in opposite hemispheres.

On the basis of these facts and conclusions we see that here, just as in nerve action generally when normal, stimulus and inhibition working together make action effective. That such is the standard type of emissive cerebration in general has long been recognized theoretically as correct; but it does not appear to have been applied very concretely. We see now that it holds for the large class of activities in the moral field. Of course, the moral does not preclude other lines of restraint.

CLINICAL CONCLUSIONS

1. These cases are evidence that a brain injury can invalidate the moral control, and practically be a cause of criminality.
2. There is a limited region in the brain that acts as controller of the individual's morals.
3. This region is sufficiently restricted in extent to warrant terming it a center. As it must be largely cortical it can be so designated.
4. This center is in one hemisphere, hence unilateral in type, as are certain other brain centers.
5. It is situated wholly in one frontal lobe.
6. It is always on the so-called silent or recessive side, *i.e.* in the right frontal lobe if the person is right-handed, and vice versa.
7. This center is inhibitive in action, emissive in type, and supermotor in the functional scale.
8. It also carries certain restraining mental attributes, such as fear, conservatism and the humane instincts.
9. Destruction or impairment of this center leaves the individual morally unguided.
10. As loss of the moral qualities can occur without loss of the intellectual, it can be concluded that the latter are centered elsewhere in the cerebrum.

In all this, one general fact stands out, supported by eleven consecutive cases (for No. XI see below), *viz.*, that lesion of the brain can cause loss or impairment of the individual's morals, and that such lesions are regularly on the right or recessive side.

This is, so far as known, the first considerable attempt to give an independent status to the right or inactive cerebral hemisphere. An additional case can here be given, which, while not in itself decisive regarding the frontal lobe, does give cor-

*Barr, *Med. Times*, 1912 p.199, says of such a girl: "She evidently had no inhibitive control of herself and frankly acknowledges that she yielded to every impulse."

roborative evidence on two important points. It shows immorality in a right-handed person, following extensive lesion of the right hemisphere, and also that this was acquired after normal maturity. The writer's attention was kindly called to this case by Dr. R. E. Blaisdell now of the Kings Park State Hospital, and the history has been most courteously supplied by Dr. Charles G. Wagner, Superintendent of the Binghamton State Hospital.

Case XI.—L. S. H. Age 22, single, admitted June 2, 1910. His personal history shows no abnormality, other than that he appeared a little backward in school, having reached the ninth grade at the age of sixteen. His morals, habits, and disposition were said to have been good. On Nov. 18, 1907, while handling a 38 calibre revolver he accidentally shot himself, the bullet entering the head through the tip of the nose and leaving the head on the upper right side of the occipital bone. The bullet was removed by operation. Paralysis of the left side of the body developed and still persists. Following his recovery from the accident he was quite peevish and childish, but was not suspected of being insane until about two years after the accident. He developed kleptomaniac and delinquent tendencies, would steal, lie, and abuse his father and mother, both of whom were very fond of him. He drove off a horse and wagon that did not belong to him. At one time he passed a forged check. It was because of these criminal tendencies that he was examined and later committed as insane.

Since being in this hospital he has at times exhibited sexual perversions. At all times he has answered questions readily and talked freely, has been oriented and his memory has probably been good. No delusions, peculiar ideas, hallucinations, or odd behavior. At times he has evaded answers to questions concerning his criminal or mischievous acts, or has denied having any knowledge of wrongdoing, whereas later it would be found that he had told some of the other patients that he had lied to the Doctor when being questioned. He could not account for his bad acts.

A summary of his physical examination shows a scar on the tip of the nose, a depressed scar on the right posterior vertex, both of which were due to the bullet wound and subsequent operation for its removal.

Subjective Sensations: Feels well, but complains of pain, numbness, and tingling of left arm and leg. Taste, smell, and hearing are normal. Pupils regular, equal, react normally.

Cutaneous Sensibility: Numbness and tingling with slight hyperesthesia and slight hypalgesia of the left arm and leg.

Motor functions: Tongue protruded to the left—movements somewhat restricted, due to short frenum. Motility of facial muscles unimpaired. Following his injury he was unable to whistle, but can do so now. Left hemiplegia. Slight atrophy of the left forearm and leg. Reflexes: Deep—or the right side normal—of left side knee jerks exaggerated—ankle clonus; Babinsky and wrist clonus; left elbow exaggerated; superficial and organic reflexes normal. Tremor: At times there is a coarse tremor of the left hand and forearm, increased upon fatigue and sudden grasping of the arm. It is not present when the arm is at rest and does not appear to be influenced by motion.

He was normally right handed.

So far, the conclusions reached are positive. The next step would be to define with exactness the location of this center in the frontal lobe. For this purpose the present material is not well suited.

The foot or posterior extremity of the three frontal convolutions has in part an assigned function, as the conjugate deviation of head and eyes. This was an early symptom in Case III, but was not known in the others. Delavan of New York, back in the eighties, "filed a claim" for the third right frontal as the center for swallowing, but it

does not appear to have been "worked" lately. In a case by Dercum (*J. N. & M. Dis.*, 1905, 106-111) the posterior portion or foot of the second right frontal was involved, with no mention of relevant symptoms (whether a right or left-hander not stated). Nor in the present series, barring Case III, is there evidence of implication of the post-frontal border.

There remains the frontal lobe forward, including convexity, orbital gyri, and mesial cortex. This is the largest remaining "silent" field in the brain. As there is no existing knowledge regarding this, approximate determinations should be timely.

The anterior pole (prefrontal as noted by Tilney and Riley) has at times been involved, according to various reports, by accidents and sinus troubles, without amoral sequence—though few cases have been followed sufficiently. This small area appears to have been included in only three (Nos. V, VI, and X) of the present cases, and in each the injury was severe enough to involve the lobe much further. It can at least be concluded that lesions of this anterior pole do not entail violence of conduct.

How much or what particular parts of the remaining major portion of the right frontal lobe are included in the promoral centers cannot be stated with exactness. Participation by the orbital gyri is not excluded. The marked anosmia on this side in Case XI (doubtless due to pressure or other direct involvement of that olfactory bulb or tract) is about the only evidence, except that from the direction and character of the primary injury in some of the other cases the orbital cortex might well have been included.

As cases of other type, involving this lobe to some extent without registering unamoral sequences, have been reported, it can be concluded that the promoral part does not include every vestige of the remaining frontal area.

In a number of such negative right-frontal cases that have come within the writer's notice, the cause was in the albas with little or no cortical involvement. In fact, of the four chief chronic processes here, tumor, abscess, hemorrhage, and trauma-scar, only the last is apt to involve the cortex directly to any extent. This also might account for some of the negative cases. To cite any exceptions in detail, whether new or from the literature, is not necessary. The positives are sufficient to outweigh any count of negatives. Nor is it necessary to decide between various explanations, but only to suggest as above a couple that may be adequate.

The middle portion of the second right frontal convolution has apparently been most often involved in the present series. Doubtless the promoral region is made up of relative subcenters, somewhat as the motor region comprises several subsidiaries.

The present cases suggest that lesions of the middle and lower right frontal incline to the quiet unamoral type, while those of the upper right frontal (Nos. II, VI, VII) are more apt to exhibit irritability and violence. But the apparent difference may depend on the severity and irritant form of the lesion.

This view of the purpose of the upper frontal convolution and the mesial cortex is strengthened by the history of two cases related to the writer by Dr. Amos O. Squire, the physician of Sing Sing State Prison. In each there was implication of the

apposed portions of both frontal lobes. Each had a record of gross criminality including murder. Neither of them (one a professional man) exhibited intellectual defect, or if any it was not sufficient to make them judicially of "unsound mind." While these two cases are irrelevant as to side, they confirm both the frontal region as a morals dominator and its inner cortex as a violence controller.

Discussion of the position of the center in the lobe can be summed up to this effect, that the middle portions of the three main convolutions have the most definite claim, with the surrounding parts next in question: the superior frontal region having perhaps a closer relation to violence.

Prospective Sources of Error in the Interpretation of Handedness.—1. The possibility of rare cases of uncrossed tracts—if there are such.

2. Cases where the primary Anlage is known only to a relative or nurse who had quietly trained the left-handed infant to be the reverse. The writer has met with two cases (not in the present series) where even the parents did not know of this.

3. There is a possibility, where the evidence shows left-sided trauma, that coincident damage may have been done to the right frontal.

4. There is nothing to prevent an occasional criminal acquiring secondarily a left-frontal lesion.

5. As persons with nominally intact brains may become criminals, it follows that in at least equal proportion persons with left-frontal lesions may develop amoral tendencies.

For these several reasons it is certain that in any very large collection of these cases there will be a few that appear to be exceptions. But this fact can in no way invalidate conclusions based on the large balance of cases, cannot count against the evidence of the great majority. It is merely a matter of good fortune that no such exception has so far been encountered.

Whether an actual left-handedness ever develops secondarily, in consequence of early injury to the dominant hemisphere, is not material to the present inquiry, though experience speaks against this as a postnatal occurrence.

Definition and Adaptation of Terms.—For the Condition: Some special designation for this condition and its subjects is desirable. Barr speaks of "amoral," and others of "unmoral." The form, *Moramentia*, from *mora* and *amentia*, is suggested as well suited to the purpose. It is applicable, intelligible and has been approved by scholars to whom submitted. A morament, then, would be one whose moral mentality is organically disabled. The derivative, *moramented*, seems also permissible.

For the Center: Character or conduct center is unsuited, as these personalities depend partly on other things. It doubtless conserves some function of a character not perfectly covered by our ordinary concept of morals. Yet the designation is likely to prevail. It might better be termed the promoral center, as this form would serve not only more definitely to label it, but would tend to avoid confusion from the various senses in which the word, moral, is employed. (The use of a term like moral suggests philosophic instead of physiologic nomenclature—or it may lift the philosophic to the dignity of the physiologic!)

For the Lobe: As this lobe, though usually the right frontal, is sometimes the left, a functional

name for it is in order. It is not the sinful lobe, but rather the antisinful. It may not be entirely a moral lobe. Nor can it longer be termed altogether silent or inactive. Whether it can properly be christened "recessive" is a question. "Psychic inhibitive" is lengthy and the lobe carries other functions. The choice can perhaps be left open, as between moral inhibitive, recessive, conservative, or some other selection.

Treatment.—Some of these cases admit of improvement. And a few can be brought to lead normal lives, whether organically cured or not. This fact is attested by several observers,* and is noted in two of the above cases. When the damage is not too great, the patient is still young, tact and care is employed, and surroundings are favorable, the prospect of accomplishing something is good.

Possibly the other hemisphere is directly substitutive. Or, the imperfect right frontal is trained to do its duty. Or, the patient (after the manner of many who in youth have sowed "wild oats") gradually feels the wisdom, as a mere utilitarianism, of conducting life the way the general public demands.

From watching the course of such cases it seems probable that there is an additional factor of eventual importance, other parts of the brain, under favorable circumstances, coming in time partially to the rescue. In the young the intellectual faculties and reason are merely developing. But as the individual gains in maturity these qualities of the intact portion doubtless become an important support to the moral side if there is enough remaining of the moral center for them to act effectively. This gain, which we can expect from the normal growth of reason, gives some ground for hope and indicates a useful line for therapeutic development.

The need of sexual control abates automatically in later years. Rarely a satyriasis then develops from damage to the moral center, or, as heretofore supposed, from irritation of a hypothetical sexual center.

The management of these cases in youth, whether private or institutional, should aim to include:

1. Environment: Life away from cities with their excitement and temptation. Discipline that depends at all on fear or physical suffering is useless and likely to do harm, besides blocking the way for other methods. Forced restraint they must sub-

*The famous case of Wigan in his "Duality of the Mind." London, 1844, does not identify the location of the offending spicule of bone. It is an early case showing that limited focal irritation can be so situated as to cause a reversal of the strongest affections, and induce suicidal and homicidal tendencies. It also registers a cure.

Many naturally think the condition hopeless, and only manageable in institutions (Näcke, 1895; Wholey, and others). It is, of course, a matter of degree of age, and of facilities.

mit to and bear well, but it counts little more unless utilized.

2. Physical Training: Activities in the open, perhaps more of the left side of the body or even of bilateral type. Ambidexterity seems a desirable aim here, at least it is certain that motation has a beneficent influence on cerebral activity, and presumably it has more effect on the side of the brain in which the motor centers are active.

3. Mental Training: To have regard for the feelings and welfare of others. To develop suitable ambitions. The adoption of accepted standards of conduct as necessary to any success in life. If religious instruction is employed, it can be of service by emphasizing the supreme importance of personal conduct.

4. Surgery: The diagnosis in simple cases is clear, surgical approach is easy, and there is little to lose, whatever the result. It consequently becomes an inviting field for the neurosurgeon. If there is a chance that the lesion is relievable it is worth taking. Where the incision is along the supraorbital line the scar will disappear in the eyebrow, or, if it can be made above the scalp line, it will be covered by the hair. But the limits of surgical repair in brain cases, and the rarity of these with surgical indications do not promise any great relief of this class by operative means.

5. Medical Care: Anemia, inanition, or other indication should be met. Recently S. J. Morris of West Virginia reports (*MEDICAL RECORD*, 1921, I, p. 438) finding a persistent thymus in each of 20 criminals autopsied. This suggests a field for both x-ray and extracranial surgery. But the matter may not be so simple. A number of the present cases were examined for thymus, but gave no evidence. And many other unmorals have been likewise negative. It is, therefore, possible that less than 100 per cent. of criminals are thymics, or that Morris' material was unusual. On the other hand, there are some reasons for thinking that in the young the developmental form may be benefited by prolonged use of thymus.

Literature.—Some references on the theoretical side have been quoted above.

The well-known crow-bar case of Harlow & Bigelow (*Am. J. Md. Sc.*, 1851) was essentially a left-frontal injury; nor is right or left-handedness stated. While the man suffered a great change of character, it does not appear from the original account to have directly involved his morals.

Extensive studies have been made in Italy, France, Austria, etc., to determine a criminal type of brain conformation (such as "splitting of the foot of the second frontal convolution, and to a less extent of the first and third," sometimes on both sides), but as yet without general acceptance. Such methods of approaching the question are so widely different from the present as to merely call for mention, except that they recognize the importance here of the frontal region. Somewhere in that literature there may be cases available for the present purpose, but as yet none have been noted. Nearest to useful are references like the following:

In Case XI of Landor (*Brit. M. J.*, 1857, I) the man was "one-eyed," but it is not specified which.

LeGrande du Saule (*Gaz. d. hôpit.*, 1878) speaks of a shocking facial asymmetry in one case.

"Moral insanity may be the outcome of apoplexy, or of a blow or other damage to the brain" (Blanford, "Quain's Dicty.," 1894).

Bogdan (*Wien. med. Wchschr.*, 1897, 1382): "We must . . . hold with Meynert, as the only right standpoint, that an ethical defect can only be considered pathologic when it can be proven a sequence of a clinically established disease of the brain, especially of the fore-brain."

Ziehen (*Neurlog. Cntbl.*, 1910, 389): Boy of 15 years, when one and a half years old he struck his forehead against a bedstead, and was over an hour unconscious. Scholarship and intelligence good. Ziehen blames both accident and heredity.

Tredgold (*Practitioner*, 1917): "Many undoubted moral imbeciles are so cunning, so plausible, and so seemingly intelligent, that mental defect, as ordinarily understood, would appear to be, and in truth, is quite out of the question."

The only previous suggestion found regarding the location of such a center referred it conjecturally to the left frontal lobe. This was made by a German writer, and appears also in Archambault's article (*Alb. Med. Annals*, 1915, xxxvi, 201), who claims that both the intellectual and moral attributes deteriorate from left frontal lesions. However, no cases are given.

While this type of case is well recognized at many of our institutions, and there are numerous references to it in articles, there is a dearth of detailed reports, and, in fact, little bearing on the particular phase of interest here. Of course, it is possible to find reported cases of injury of the left frontal lobe, more such apparently than of the right. But so far not one has presented the unmoral type. In other cases, and that show such manifestations, it is only stated to be in the frontal region, without mention of the side.

Negative cases of right-frontal lesion can only count against the positive when and to the extent they show that there are portions of this lobe, which can be injured without unmoral manifestations. Bad conduct must always be in part a matter of circumstances. In a well-managed hospital ward, for instance, there is little occasion for incidents of this character.

Naturally it is as yet only the more pronounced cases, with gross moral and anatomic defect, that find their way now and then into the literature. Slight forms with limited lesions are likely to prove more instructive, and practically these minor cases must come from private rather than institutional observation. The world necessarily has to wait for the physician to open up this field and point out its significance. He alone has the combination of training and access to the requisite material (cases, references, advisers). No one else is circumstanced to take the initiative. When the basic outline is made out, the findings become generally available and can be taken up by others for detailed application (to be briefly considered in a subsequent paper).

Acknowledgments.—Rarely does the preparation of a paper involve such great obligations. Without assistance it could not have materialized. Dr. R. M. Elliott of the Willard State Hospital gave an all-important impetus, and utilized his resources in many ways. Dr. Christian of Elmira not only granted use of cases, but sought them out, and later

supplied drawings. Dr. Winfield of Brooklyn aided with material. To these colleagues, to others mentioned in the text, and to many friends the writer wishes to express his profound indebtedness.

54 LEFFERTS PLACE.

SUPRAPUBIC PROSTATECTOMY: A SIMPLIFIED METHOD.

By EUGENE H. EISING, A.M., M.D.

NEW YORK.

VISITING SURGEON TO THE SWENHAM HOSPITAL AND HOSPITAL FOR JOINT DISEASES.

THE essential features of prostatectomy are two-fold. First, the complete removal of the obstruction to urinary flow; and second, the restoration of complete and perfect bladder function. Any operation which fails in either of these two essentials cannot be considered as successful.

By the perineal approach the complete removal of the obstructive prostate can be readily accomplished, but by this method, the second essential, that is, the restoration of perfect bladder function, fails in a much larger percentage of cases than after the suprapubic operation. Why this should occur is readily seen when one considers the various structures that must be traversed in the approach to the prostate and which to a greater or less degree become traumatized in the manipulations.

For this reason it may be prophesied with reasonable certainty that the perineal operation must eventually give way to the suprapubic, at least in the hands of the great majority of surgeons.

The operation of suprapubic prostatectomy is conveniently discussed in four divisions. (1) The preparation of the patient, (2) The cystotomy, (3) The prostatectomy, (4) The postoperative treatment.

1. *The preparation of the patient* is of no mean importance and a close observation to details will aid in establishing a smooth convalescence and in some instances will save life. It is wise in all cases to make a routine x-ray examination of kidneys and bladder; it acquaints the surgeon with conditions present and is of great importance in prognosis. Calculus in the upper urinary tract demands correction after the cystotomy and before the prostatectomy. Rest in bed for a period of three to five days with an in-dwelling catheter is a good procedure, or what is preferable, when it can be done, is catheterization every two or three hours. This reduces the amount of residual urine, permits the bladder to resume its normal tonicity, and relieves back pressure upon the kidneys. This alone often has the effect of restoring strength and well-being to the patient and sometimes removes the indication of delay between the cystotomy and the enucleation of the prostate. When cystitis exists the catheterization should be accompanied with daily irrigations of a mild antiseptic solution until the day of operation. If there is no cystitis, there is little to be gained by irrigation.

Some functional test of the kidney efficiency should be performed. As an indication for or against operation much reliance need not be placed upon the result of this test for two reasons, first, because the operation is usually an imperative one and must be done even in the face of poor efficiency;

and second, because the efficiency frequently improves subsequent to the operation. A carefully determined daily urea output on a mixed diet is perhaps as good as any indication of the joint efficiency of the kidneys.

A cystoscopic examination should be made as a routine measure. It is sometimes impossible in the presence of stricture or acute retention with hemorrhage. The examination acquaints the operator with the configuration of the enlargement and the degree of the vesical or urethral encroachment, and in some cases will place him on guard in the presence of carcinoma. Not that carcinoma can be diagnosed from its appearance through the cystoscope, but that in the absence of endovesical enlargement and with no median lobe to account for, the obstruction, carcinoma will not infrequently be found. Twice I have seen the endoscope reveal indications of inflammation in the prostatic urethra in old patients with long-standing obstruction. Misinterpretation of these indications led to an attempt at prostatectomy, when a chronic prostatic abscess was found.

The use of large quantities of water and the administration of urotropin or one of its analogues is generally considered advisable. Heart and arterial tonics may be of some benefit, but the mortality in these cases depends rather upon the condition of the kidneys.

2. *The Cystotomy.*—Various questions arise in the minds of workers in this field as to the wisdom of this or that variation in the technic, any one at times giving good results. The patients, however, who are to be relieved by prostatectomy are all past middle life and many of them are old and feeble; that technic is best which best meets the needs of the individual. The cystotomy is very easily accomplished under local anesthesia in most patients, and in patients in whom it is decided to perform the operation in two stages it is distinctly the one method to be preferred. If, however, the patient is very corpulent or is nervous and irritable or gives the impression of lacking so far in self-control that it is believed that he will strain and force down the peritoneum and make tense the recti muscles, a general narcosis is much to be desired. If the complete operation is determined upon, the general narcosis is better given at once.

Before beginning the operation a catheter is placed in the bladder, and the bladder is washed. The bladder is permitted to empty itself through the catheter, and the catheter is left and fixed in place. To the distal end of the catheter is attached a simple inflating apparatus, consisting of an atomizer bulb and a glass connecting-piece.

The incision is median, beginning about half an inch above the symphysis and extending about two inches or a trifle more. The recti muscles are separated and prevesical fat presents in the wound. The anterior fold of peritoneum will sometimes present in the wound and is readily stripped back. The fat in the space of Retzius is sometimes abundant and at others almost deficient, and is to be treated much the same as perinephric fat; it is carefully separated over the bladder and when veins present they are clamped and ligated. An assistant now slowly inflates the bladder with air until the inflated organ is distinctly felt to rise in the wound beneath

the finger of the operator. Air distention has the decided advantage over water distention, as no flooding of the wound occurs. It has also the advantage of no distention as practised by some, inasmuch as it makes the operation easier and less liable to be attended by the complication of opening the peritoneal cavity. If the peritoneum is opened it should be at once closed with a tight catgut suture and the operation continued after protecting the suture line with gauze. It is the practice of some operators to lay gauze packings about the bladder, protecting the prevesical space and the line of incision before opening the bladder. This has been found entirely useless, as no infection of this space occurs unless undue trauma is inflicted. The use of anchorage sutures as tractors for the bladder wall has been abandoned by deft operators, but in the hands of the less skilled is a safeguard and had better be employed. The incision in the bladder should be made at a high level for the reason that when the bladder is contracted the incision will be dragged downward, and if planned too low, will contract behind the symphysis and to some extent interfere with drainage. If no anchor sutures are used the point of the knife is rapidly passed into the distended bladder and an incision is made about an inch downward; the index finger of the left hand is quickly passed into the opening before the knife blade is withdrawn. If this manoeuvre is not dextrously performed, the bladder will collapse and much difficulty may be encountered in finding the opening.

The opening in the bladder can readily be stretched to admit two fingers of the right hand. A stretched or torn wound in the bladder heals more rapidly than an incised wound. The reason for this is that the bladder is a musculofibrous organ, in which the muscular fibers determine the direction of the tear, and their subsequent contraction hastens the closure of the wound. I am thoroughly convinced of the importance of this small point in technic and believe that several weeks can often be saved in the convalescence if the wound in the bladder is extended by tearing instead of by cutting.

If it is desired to wait before performing the prostatectomy a large gauge rubber tube surmounted by a snugly fitting collar of larger sized tubing is inserted into the bladder, care being exercised that the lower end does not impinge on the bladder wall. The tube is fixed in place by means of a single suture through the collar of the tube to the aponeurosis. No sutures are placed in the wound. Gauze packings are placed lightly above and below the tube in the wound and a dressing is applied.

3. *The Prostatectomy.*—If it is decided to proceed with prostatectomy, two fingers of the ungloved right hand are placed in the bladder. The general contours of the prostate are recognized with the finger, the size of the lobes, their location, their hardness, the presence of a median lobe, and the degree of dilatibility of the internal urethral orifice. Two fingers of the left hand are passed into the rectum and the prostate is firmly brought into reach of the fingers in the bladder. It will be found that the simple device of inserting two fingers into the rectum, instead of one, makes the enucleation very much easier and more thorough. With only one finger in the rectum, the prostatic mass cannot be

prevented from rolling away from the enucleating fingers, but the two rectal fingers secure it firmly.

Rarely is it necessary to incise the capsule with the knife or finger nail. The index finger is inserted into the internal urethral orifice, if the catheter has not yet been withdrawn it will serve as a guide to the orifice; the catheter is then withdrawn. With the finger in the urethra a firm but gentle pressure, usually downward, sometimes laterally, will find a path of lesser resistance. The prostatic capsule is always thinned out and weakened in this region, owing to the growth of the gland in a vesical direction. This path of lesser resistance will guide the finger to the capsule of the gland, and then bearing in mind the anatomical structure of the gland, the cleavage is continued to the median line anteriorly. It is sometimes possible to follow this same layer of cleavage across the median line, or else it may be necessary to find a new point of entrance. The entire prostate should be removed. The gland can sometimes be removed *en masse*, more frequently in large lobules, and sometimes in numerous small masses. The ease with which enucleation is accomplished is very variable and depends upon various factors. The normal prostate and the carcinomatous prostate are practically impossible to remove by enucleation. They can be avulsed, usually in small pieces, but there are no distinct and separable layers of cleavage to guide in their removal. The so-called hypertrophied prostate is an adenoma of the prostate. This adenoma may be either pure or fibrous, or any admixture of the two. The more nearly purely adenomatous, the easier is the enucleation; the more purely fibrous, the more difficult.

The enucleation of the prostate necessarily inflicts laceration and other injury upon the urethra. The injury sustained by the urethra is not always the same, and may be slight or severe according to the nature of the case and the manner in which it is handled. Nature treats beneficently almost any injury to the prostatic urethra, so long as the triangular ligament is not injured. It is ordinarily stated that the floor of the prostatic urethra is firmly held down by connective tissue and that only that portion behind the veru montanum comes away with the gland. This may be usually the case, but it is certainly not true of all cases. It happens not infrequently that the veru montanum and lateral sulci can be distinctly seen upon cutting the removed gland. When this happens the patients make a complete recovery with perfect bladder function.

After the enucleation is completed, the rectal hand is withdrawn and the glove removed. Meanwhile the fingers of the right hand remain in the capsule of the gland. A long strip of gauze is guided on a dressing forceps and packed into the prostatic capsule, and maintained there until active bleeding is pretty well controlled. If the bleeding is checked, this packing may be allowed to remain, or a fresh one may be inserted and left in place. Active bleeding comes from one of two sources: (1) from the free edge of torn mucous membrane, or (2) from portions of retained gland tissue. The prostatic plexus lies outside of the capsule and does not contribute to the bleeding unless there remains unre-moved gland tissue, acting in much the same way as does retained placental tissue. The chief source

of hemorrhage is from the torn edge of mucous membrane; this bleeding, except in rare instances, can be controlled by packing held well in place for a few moments. After the bleeding is controlled the packing can be removed and left out, but it seems an additional safeguard to leave it in place, with one end of the gauze issuing out of the wound. Just how long this gauze serves as an efficient packing is difficult to answer, as it soon becomes urine soaked and is likely to become dislodged. A tightly placed packing is the cause of considerable post-operative pain and also delays the contraction of the prostatic capsule, which ensues at an early date.

A tube is inserted as in cystotomy and no irrigation whatsoever is employed. Usually no sutures are applied to the bladder wound unless the opening is unusually large. Small gauze drains are inserted above and below the tube in the abdominal wound and a dressing is applied. In bed the tube is connected to a bottle as after the operation of cystotomy. Complicated syphon drainage has long been discarded as unnecessary and harmful.

Usually a fair amount of oozing of blood occurs which shows mixed with urine in the receptacle alongside of the bed. The sanguineous character of the urine disappears usually after the second or third day, but sometimes persists until the fifth day.

The fibrous capsule which has undergone undue distention from the growth of the prostate is prone to speedy contraction after the removal of the gland. It has seemed to me on several occasions that I could detect an immediate contraction while my fingers still remained in the empty capsule. In the course of the first week or ten days the contraction is very marked, and can sometimes be measured by means of the catheter.

There is no doubt that the source of many of the complications formerly seen was faulty technic both inside and outside of the bladder. The gland should not be avulsed, it should be enucleated, and no great force is necessary. Outside of the bladder, there should be no laceration or stripping of the mucous membrane from its extravescical attachments. The suprapubic wound should be guarded from any unusual and unnecessary trauma. The anterior bladder wall can be very easily stripped from its loose adhesions in the space of Retzius and from the symphysis and cause pocketing that will become infected and may lead to serious consequences.

4. *The postoperative treatment* in an uncomplicated case is very simple. Gentle irrigation through the suprapubic tube once or twice a day, in order to remove any loose clot or exudate, is all that is necessary for the first and second day. Usually on the third day the tube and the capsular packing may be removed and the bladder irrigated through the wound. If the urine is still markedly sanguineous the packing may be left in place for a longer period. A loosely applied strip of gauze is placed in the wound and a dressing of any absorbent material. The dressing will require frequent changing. No urethral instrumentation is necessary at any time. The wound may be expected to be completely closed in three weeks.

After prostatectomy, even though no cystitis had previously existed, the urine remains turbid for a number of weeks. This turbidity gradually disappears with or without any medication.

After the complete contraction of the capsule of the prostate, the true sphincter reassumes its function; this usually occurs some time along the second week following operation while the suprapubic wound is still open, and at first is accompanied by some pain.

Although carcinoma of the prostate will be suspected from the rectal feel of the gland in most cases, at times the revelation will only be made at the time of attempted enucleation. If the neoplastic deposits have become at all extensive, the hard shot-like feel must at once give warning. A carcinomatous prostate, if at all advanced, is so thoroughly cemented to the pelvic walls, and layers of cleavage are so obliterated, that its removal becomes a most difficult and oftentimes dangerous procedure. This, together with the fact of the increased rapidity of growth after a partial removal, should urge the surgeon to desist from forcibly removing a prostate after being convinced of its malignant nature.

35 WEST 51ST STREET.

WHY NOT ELIMINATION?

By GEORGE L. SERVOS, M.D.,

RENO, NEVADA.

EDITOR, "WESTERN MEDICAL TIMES."

EVERY now and then we pick up some medical journal and read an account of a case of influenza, encephalitis lethargica, or some other acute infection, and when it comes to the matter of treatment we see physicians going back to the time-honored and time-worn technic of meeting symptoms.

We hear much of diagnosis, although in some instances it is rather frankly admitted that an "unknown infection" is at the bottom of things. We also hear much of the severe intoxication accompanying such infection, known or unknown, but when the matter of treatment is reached all these things are apparently forgotten, and the doctor meets and endeavors to combat symptoms, allowing the cause to go merrily on, with the production of further effects. In a very large percentage of instances the endeavor seems to be, in some way or other, to kill the bacteria. Were this possible, it might be likely possible that the host might perish, as well.

During the influenza epidemics of 1918-1919 and 1919-1920 we gave considerable heed to the various lines of treatment suggested and the results attained from each. There were some men who gave no attention to the cause, but rather endeavored to overcome the symptoms, through masking them. Febrifuges were given that the fever might be lowered, opiates were administered, sometimes along with the coal tars, that the pains might be alleviated and numerous antiseptics were exhibited, with the hope that at least some of the bacteria might be destroyed.

It was a noticeable fact that where symptom treatment was employed the mortality rate was high, in some instances very high.

There was another set of doctors who did little or nothing. They insisted that medicinal agents were worthless, so why give them. They told their patients to go to bed and stay there until well. In a way they, to our mind, excelled some of the meeters of symptoms to a certain extent. They at least

did not check normal elimination through the use of opiates, nor did they lower the vitality of their patients by the exhibition of the coal tars. But they did not hasten elimination, and their death rate was altogether too high.

Subsequent to the epidemics mentioned it was noticed that the patients of both of the above-mentioned classes of physicians showed a considerable number of sequels. We who make many insurance examinations have been encountering heart and kidney lesions in quite considerable numbers, as well as some of the lungs, and many of these among the young.

There was another class of doctors who ignored symptoms, excepting as signboards to designate to them whether or not improvement followed in the wake of their endeavors. They recognized the fact, at a very early date, that they had a virulent infection with which to deal. They recognized the fact that the toxins piled up with great rapidity and those toxins were retained within the economy through the stoppage, to a greater or less extension of normal function, this being due to a lowered vitality. They also discovered that a very considerable number of their patients were carrying an acidosis to greater or less degree. To their mind it was not a matter of knowing the exact bacterium causing the disease; of giving more than passing attention to symptoms, or doing little else than clearing the system of both cause and effect at the earliest moment possible. These men began employing eliminants; carefully at first, but later in what have been called heroic doses. They began seeing satisfactory results immediately and, as a rule, their patients did not remain bedridden for long periods, and after the subsidence of the acute stage of the disease, few if any showed a single sequel.

This latter class paid but scant attention to symptoms and exhibited not one single drug to directly remove or relieve a single one of them. They simply removed the toxins and as much of the cause as possible, alkalinized the system to a very considerable extent, and the disease "died aborning," as might be said. Those symptoms simply quit of themselves, for there was nothing left to cause them.

Now comes encephalitis lethargica, and we see the same seeming error in the treatment of symptoms entering—a few are using the eliminants and obtain the same results as occurred in influenza. The symptoms are met and alleviated in spite of the fact that those who follow such technic admit that they are dealing with an infection, or at least a something, that is the cause of a marked toxemia. But still they give bromides, chloral, coal tars, opiates, and the host of other alleviators of symptoms, or antiseptics of one sort or another, hopeful that their patient will recover; but from reports it is rather apparent that the mortality rate is considerable under such technic and that the patients are left with uncomfortable sequels even if they do recover from the acute stage.

Another set of men considered encephalitis lethargica similar to influenza in many of its manifestations. Anyway, it was apparently an acute infection with a pronounced intoxication, and it was likewise apparent to them that the toxins were not being eliminated. Profiting by their experi-

ence with influenza, these men employed eliminants of an alkaline nature, pushed to the limit, and with the same happy experience as in influenza. Their patients recovered quickly and with few, if any, sequels.

A few days ago a doctor said to us that lobar pneumonia would not be such a horrible thing if we could only lessen the toxemia. We suggested alkaline eliminants to him, they to be exhibited in sufficient dosage, and he intimated that we were foolish, for what did we do about the high fever, the heart condition, et cetera. We admitted that we would probably disregard all symptoms, in so far as they might be indications for treatment, and that it was our belief those symptoms would occasion little worry, were the cause, the toxemia of which he spoke, promptly removed.

The theory of enforced elimination in acute infection accompanied by toxemia and more or less acidosis may be all wrong, but after seeing the ease and comfort given patients through such procedure in our own practice and that of others, we feel that we can afford to be called fools, or worse, by those men who will not seemingly mix some common sense with medicine and who apparently will not accept a single hint, unless it arises from the lip or pen of some so-called authority.

WASHOE COUNTY BANK BUILDING.

SOME CASES OF DIPHTHERIA WITH THEIR TREATMENT.*

BY LESTER CURTIS, M.D.,

CHICAGO, ILL.

I AM presenting the following facts on the advice of friends, who consider it my duty to make the report. I am in no sense opposing antitoxin, the great value of which I fully appreciate, but I believe the method here described is an addition to our armamentarium and in a large proportion of cases is all the treatment needed. A bit of history may make clear what I have to say.

In the Autumn of 1890 I was called to a mother and two daughters, one about thirteen and the other nine, down with diphtheria. On the tonsils of the mother and of the younger girl were patches of membrane about the size of a nickel. These two cases did not seem serious. But the condition of the older daughter was quite different. Her pharynx and tonsils were entirely covered with a greyish putrid membrane which filled the nasal cavity and protruded from both nostrils.

Thirty years ago antitoxin was still unknown and the methods of treatment in use were unsatisfactory. Cases of diphtheria with membrane in the nasal cavity were not new to me. I had used the best methods then known to the profession in treating such patients but they had all died. The prospect in this latter case therefore was not flattering. Some better treatment must be devised. At that time the Klebs-Loeffler bacillus had already been shown to be the cause of diphtheria. It had also been shown that the disease in the beginning was purely local, the serious after symptoms being caused by absorption of poisons produced by the growth of the bacilli. If that were the case destruction of the bacilli ought to arrest the disease. The fault with the former treatment then, must have been that the disinfection had not been thorough enough. I resolved to make it more thorough. Accordingly a solution of bichloride of mercury, 1/2000, was applied to the throats of all three of the patients with a syringe having a long nozzle, which

would reach far into the mouth, close to the membrane. Some force was used in making the injection. In the case having the more extensive membrane in the nasal cavity, in addition to the throat treatment, the tip of the syringe was inserted into each nostril and the pressure continued until the fluid appeared behind the soft palate. The applications were made every two hours night and day. The results of the treatment were immediate, and in all the cases eminently satisfactory. In the two milder cases the membrane melted away and the next day showed only a few scattered dots. These patients passed rapidly on to recovery.

The severest case was more obstinate. But the third day there was expelled from her nasal cavity a mass of membrane, in size and color, resembling a small oyster. After this occurrence, the nose and pharynx were clear, except for a deep ulcer on one tonsil, which required stimulation before healing. As might have been expected, this patient progressed more slowly than the others. Fortunately her heart's action remained normal, but in a week or ten days disturbances of accommodation appeared in both eyes. Then followed difficulty in deglutition and a peculiar husky voice in speaking, and shortly afterwards, weakness and lack of coordination in the muscles of the legs. These symptoms, without much treatment, gradually improved and by the end of five or six months they all disappeared and the patient regained her usual health except that her throat remained sensitive.

Before going further I would like to call attention to the technique of the treatment. This technique is of prime importance. You will notice that a spray was not used. Much experience with the spray had shown me that it was ineffectual in such cases. A spray spreads over the membrane only a minute quantity of the solution, which does not penetrate below the surface and is diluted and immediately washed away by the fluids of the mouth. The deeper parts in the meantime are untouched by the solution, and the bacilli there remain alive and continue their evil work. The same objection holds against gargles and swabs, as also against a syringe with a pepperbox nozzle; they are not thorough enough. On the contrary, the narrow stream from a syringe with one opening held near the surface, and projected with force, penetrates the membrane and searches the deepest parts, reaching even into the follicles. No bacillus can escape repeated injections of this sort.

Soon after my experience with these three cases I was called to a young girl who had a small greyish patch on each tonsil. The case was diagnosed as diphtheria, and the bichloride solution, 1/2000, was applied to the throat with a syringe every two hours, in the way above described. On my second visit, five or six hours later, in place of the patches on the tonsils, only a few white dots were seen. The next day there was no trace of membrane and the patient had every appearance of convalescence, but as a matter of precaution the applications were continued at longer intervals and two or three more visits were made, before the patient was discharged as entirely recovered. No sequelæ followed.

Since then I have been in charge of many cases of diphtheria. Though I have been on the watch for better methods, my patients have all improved so rapidly on the treatment described that I have never felt justified in changing to something which seemed more cumbersome and gave no better results.

The method has been unsuccessful in one case only, that of a vigorous boy of about fifteen. When I first saw him he had been without medical treatment for about four days from the beginning of the disease. I found the tonsils and back of the pharynx entirely covered with a greyish, putrid membrane. There was in addition, swelling and tenderness of the glands of the

*Read before The South Side Branch of The Chicago Medical Society, February 24th, 1921.

right side of the neck and a friction sound over the right lung. A gland in the neck was opened the next day and discharged nearly a teacupful of putrid pus. By this time there were clear indications of an abscess of the lung. The bichloride solution was applied to the throat and the membrane speedily cleared up, and the throat became entirely clean. The abscess however continued to develop. The consultant who was called in, advised no essential change in treatment. The boy finally died, as I believe, from the lung abscess which had begun before I saw him, and as a consequence of neglect.

One more case and I have finished. About a year ago (Oct. 13, 1919), I was called to a young woman, a teacher in one of the public schools of Chicago, twenty-four hours after the first symptoms had appeared. When first seen she had a temperature of 104° and a greyish adherent patch of membrane on each tonsil nearly the size of a quarter of a dollar, with the other usual symptoms of diphtheria. The throat was at once syringed with a 1/2000 bichloride solution and directions left for repeating the syringing every two hours. Six hours later the membrane had gone, leaving only a few small points over the follicles. The temperature had sunk to slightly under 101°, swallowing was easier and the patient was feeling much more comfortable. The treatment was continued. The next morning, twenty-four hours after my first visit, the throat was entirely clean and the temperature slightly subnormal. The following morning the temperature was normal and all traces of the disease were gone.

A few minutes after the first treatment, I wiped the patches with a wisp of absorbent cotton, which was conveyed to the Board of Health, and reported as being from a case of suspected diphtheria. On the third day afterwards notice was received from the Board of Health that no diphtheria had been found in the specimen. This means in my opinion, that all the bacilli had been killed by the first application.

The School Inspector, said to be a man of large experience with diphtheria, called the second day, in my absence. He examined the patient and inquired into the treatment, which seemed new to him. His opinion was that the case undoubtedly had been diphtheria but was not then. He did not quarantine the house. He allowed the sister, also a teacher, who was living with the patient, to go back to school on the third day; after disinfection and change of clothes. The patient herself returned to work on the tenth day after I first saw her.

These few cases will, I trust, make the method or treatment clear. The other cases that I have seen are so nearly identical with these that to give more would be superfluous.

I think these cases show that the bichloride is effective. It is quite possible that at a critical time antitoxin may be out of reach or obtainable only after ruinous delay. Bichloride may be always at hand and ready for immediate use, an important consideration where time is precious. It is prompt in its action. It is safe; it is not to be swallowed, but, in the strength used, if a little should slip down no harm would result. It may also be well to remember that there is no danger from contamination or faulty preparation. It has no unpleasant taste and causes no irritation or inconvenience of any kind. Even children do not object to it.

I should like to have the subject discussed, and should be glad to have the method tried by others. I believe that if used in the way described it will be equally successful in other hands.

1031 EAST 50TH STREET.

Immunity to Measles in the First Six Months of Life.—Weill and Bocca relate an episode in which thirty-three infants were simultaneously exposed to measles and but twenty-two infected. The eleven immunes were all under the age of six months, while the victims were all above that age.—*La Presse Médicale*.

A CONCEPT OF X-RAY PATHOLOGY.

XV. X-RAY LITERATURE.

By A. J. PACINI, M.D.,

WASHINGTON, D. C.

CHIEF OF X-RAY AND LABORATORY SECTION, HOSPITAL DIVISION,
U. S. PUBLIC HEALTH SERVICE.

IN the preparation of the articles of this series, the works below enumerated and the studies supplied by the roentgenologists whose names have been mentioned were freely consulted and in many cases quoted verbatim. In addition Osler's "Practice of Medicine," Barker's "Monographic Medicine," Norris and Landis' "Diseases of the Chest and the Principles of Physical Diagnosis," and Speed's "Fractures and Dislocations" were consulted freely and quotations made therefrom on subjects dealing with x-ray.

ARCELIN, F.: "L'Exploration Radiologique des Voies Urinaires,—Lithiases et Projectiles de Guerre." Masson et Cie. Editrices. Paris, VI, 1917.

THIS book deals with the x-ray exploration of the urinary tract. Its first chapter is historic. The second considers the material discussed in the remainder of the book. The third and fourth chapters enter into a consideration of the technique of the x-ray examination. The fifth chapter treats of the general interpretation. Chapter six discusses the roentgenography of the kidney or renal silhouette; and also the ureters and the bladder as outlined by pyelography. The seventh chapter enters into an elaborate discussion of kidney stones and their x-ray diagnosis. The book closes with chapters eight and nine in which projectiles and foreign bodies are studied.

ARTHUR, DAVID, and MUIR, JOHN: "A Manual of Practical X-Ray Work." Published by Reiman Company, New York City. Second Edition, 1917.

ARTHUR and MUIR's book may be divided roughly into three parts: The first, a discussion of the technique of the investigation in so far as apparatus and photography are concerned. This occupies more than one-half of the book. The second part is devoted to x-ray diagnosis. This section is moderately illustrated with diagrams and reproductions of roentgenograms. Most of the pictures are exposed from underneath rather than from above, a custom more commonly practised abroad than in America. The principles of diagnosis, unnecessarily brief, are reasonably well presented. The last eighth of the book is devoted to x-ray therapeutics. This section is not as full as the subject of x-ray therapeutics imperatively demands.

BARCLAY, ALFRED: "The Alimentary Tract—A Radiographic Study." Second Edition, 1917. Published by The Macmillan Company, New York.

FOLLOWING an introduction Barclay successively discusses the technique, the routine examination, diagnoses of affections of the esophagus, the normal stomach, the pathological stomach, gastric ulcer and hour-glass stomach, carcinoma of the stomach, various gastric conditions, the small intestines, the etiology of gastric and duodenal ulcers, the large intestines, some conclusions and a tabulation of cases. Several excellent thoughts are advanced, more especially the studies dealing with the ileopyloric reflex. A remarkably full bibliography is included at the end of the book. The bibliography points to papers of general pathological interest as well as to papers and books dealing especially on gastric intestinal studies. Some American roentgenologists are quoted in the bibliography, but not as many as merit would demand.

BÉCLÈRE, ANTOINE, COTTENOT, PAUL, and LABORDE, Mme.: "Radiologie et Radiumthérapie, xxxii, Traité de Pathologie Médicale et de Thérapeutique Appliquée." A. Maloine et Fils, Paris, 1921.

THIS is a general textbook on roentgenology to which there is added a section on radiumtherapy. In general the illustrations are poor and few; although the text is in every way modern and presents sound principles of roentgen ray diagnosis. The roentgenologist thoroughly familiar with French would be interested in this work; but its character is so general as to pre-

clude the necessity of adding this book to the library of one already supplied with English texts of standard authorship.

BRAGG, W. H., and W. L.: "X-Rays and crystal structure." Third Edition, 1918. Published by G. Bell and Sons, Ltd., London.

This excellent book is of little value to the x-ray interpreter. It presents some exceptionally keen studies in x-ray physics, more particularly on x-ray spectrometry, crystal structure, x-ray spectra, the analysis of crystal structure, and the analysis of Laue photographs. It is a useful text to those interested in the technical aspect of roentgen ray possibilities.

BYTHELL, W. J. S., and BARCLAY, A. E.: "X-Ray Diagnosis and Treatment.—A Text-Book for General Practitioners and Students." Published by Henry Frowde, Oxford University Press, and Hodder & Stoughton, London, 1912.

This book is a sort of atlas. There is first a general discussion of the principles of roentgen ray diagnosis of a particular region; and following the discussion a number of excellently reproduced photographs illustrate the more important conditions. The last section of the book deals with x-ray therapeutics. This section is entirely too scanty for x-ray therapists. The book is considered more valuable for its store of general interpretative information, than for its therapeutic applications.

CARMAN, RUSSELL D.: "The Roentgen Diagnosis of Diseases of the Alimentary Canal." Second Edition, Revised, 1920. Published by W. B. Saunders Company, Philadelphia and London.

CARMAN's text on the gastric intestinal tract requires little comment. It is excellently prepared and contains valuable and authentic information presented in a most readable form and illustrated with pertinently applicable reproductions. Each chapter closes with a list of carefully selected references. It presents an exceptional bibliography. The book should form a part of every x-ray library, not alone because of its intrinsic merit but because of the compiled bibliographic references.

CHRISTIE, ARTHUR C.: "A Manual of X-Ray Technic." Second Edition, Revised and Enlarged, 1917. Published by J. B. Lippincott Company, Philadelphia and London.

CHRISTIE's "Manual of X-Ray Technic" is a splendid elementary introduction to roentgenology. It presents the fundamental basic principles of roentgenologic investigation and discusses briefly and with authority general interpretation. The manual is exceptionally useful for those who are just beginning the study of roentgenology.

DWIGHT, THOMAS: "Variations of the Bones of the Hand and Foot.—A Clinical Atlas." Published by J. B. Lippincott Company, Philadelphia and London, 1907.

DWIGHT's Atlas is the only authoritative American treatise that deals with any degree of minuteness on the variations of the bones of the hands and feet. Variations in the bones of the hands and feet are not only interesting but are in many instances important for the roentgenologist. This is true especially in medicolegal cases, as in deciding whether an apparent solution of continuity of a carpal scaphoid is the result of trauma or is a congenital bipartite variant. The roentgenologist should be familiar with the usual variations discussed by Dwight. Dwight's references to the literature are fairly complete. The atlas is most valuable in the library of the roentgenologist.

ELY, LEONARD W.: "Diseases of Bones and Joints." Published by Surgery Publishing Company, New York, 1914.

This book, while not essentially an x-ray book, presents one of the most lucid discussions of bone pathology anywhere obtainable in the English language. In the article on osteopathy, of this series, the bone pathology described is in many instances taken verbatim from Ely's "Diseases of Bones and Joints." The discussion of the subject is exceptionally clear, concise, and authoritative. It is imperative that the roentgenologist be thoroughly familiar with this book, if a proper conception is to be gained of the changes affecting bones and joints in disease.

GAGE, HAROLD C.: "X-Ray Observations for Foreign Bodies and their Localization." Published by C. V. Mosby Company, St. Louis, Mo., 1920.

This little manual deals with the localization of foreign bodies by the use of the x-ray. Various standard methods are discussed and in addition the author elaborates on the method of cross-section localization by three intersecting lines. The use of bromide paper in the place of x-ray plates for recording daily the x-ray progress of fractures is mentioned. The book is valuable for the military roentgenologist and also for the industrial roentgenologist who has to do with the localization of foreign bodies.

GREEN, A. A. RUSSELL: "An X-Ray Atlas of the Skull." Published by Longmans, Green and Company, London and New York, 1918.

This atlas of the skull affords a very brief discussion of the apparatus involved in the technique of cranial roentgenology. The plates that are reproduced are good. Some of the plates are colored, different colors indicating different anatomical levels and landmarks of the skull. The book is of some value to the roentgenologist concerned with the study of the cranium.

HIRSCH, I. SETH: "The Principles and Practice of Roentgenological Technique." Published by the American X-Ray Publishing Company, New York, 1920.

HIRSCH's text on the principles and practice of roentgenological technique is the most complete treatise available dealing entirely with the technique of roentgen ray examination. It is divided into two parts, the first dealing with the principles of technique, including a discussion of electricity, induction apparatus of various types, portable induction apparatus, the discovery of the x-ray, Crooke's or gas tubes, hot cathode or electron tubes, the cathode discharge, the x-ray and its properties, the production of x-rays and the measurement of x-rays. This is followed by the second part of the book which treats of the applications of these principles, discussing fluoroscopy, radiography, radiographic methods, the silver bromide plate, postures and position, standard positions, exposure, the development of the plate, the examination of the plate and the general organization and administration of x-ray laboratories. The book is profusely illustrated and is everywhere exhaustive in its discussion of the subject matter. It is indispensable to the x-ray library of every roentgenologist.

HOLMES, GEORGE W., and RUGGLES, HOWARD E.: "Roentgen Interpretation.—A Manual for Students and Practitioners." Published by Lea & Febiger, Philadelphia and New York, 1919.

WHAT Doctor Hirsch accomplished in his textbook on the principles and practice of roentgenological technique, Holmes and Ruggles, in a similar way accomplished in their text on roentgen interpretation. There are several unusually creditable features of this work. First, the briefness yet authoritative in exposing the fundamental principles of roentgen ray interpretation; then the well-chosen bibliographic references that conclude each chapter, finally the clearness with which the pictures reproduced portray the particular type of pathology under discussion. The volume is small and handy. It is useful to the beginner in roentgenology for the x-ray essentials of interpretation that are expounded; and for the advanced roentgenologist, for the full and carefully selected bibliographic references. This book should form a part of every x-ray library.

IVY, ROBERT H.: "Interpretation of Dental and Maxillary Roentgenograms." Published by C. V. Mosby Company, St. Louis, Mo., 1918.

This book is useful from which to gain a general conception of dental roentgenology. Since this book was published many important advances have been made in the technique of dental x-ray examinations, more particularly with reference to the types of dental machines and dental x-ray tubes now used. This book is moderately useful but not indispensable.

KAYE, G. W. C.: "X-Rays." Second Edition, 1917. Published by Longmans, Green and Company, London and New York.

KAYE's book is an exposition of x-ray physics both experimental and applied. It has no immediate practical value for the roentgenologist interested only in cultivating an ability in interpretation; but it pre-

sents many facts that stimulate thought in connection with the elaboration of physical x-ray apparatus. This book is only of general interest to the roentgenologist who is desirous of completing his information in the possibilities of the physical exploitation of x-rays.

KNOX, ALICE VANCE, and ROBERT: "General Practice and X-Rays." Published by A. & C. Black, Ltd., London, 1921.

THIS new book is for the English profession what Holmes and Ruggles is to the American profession. Its general scope is practically similar, excepting that it includes a part on x-ray physics and x-ray apparatus. The interpretative section leans more toward an elementary presentation of the essentials of the usefulness of x-ray diagnosis in various diseases. It is a good book, one with which the roentgenologist should be familiar, but not indispensable to an x-ray library.

KNOX, ROBERT: "Radiography in the Examination of the Liver, Gall Bladder, and Bile Ducts." Published by C. V. Mosby Company, St. Louis, Mo., 1920.

KNOX's monograph on radiography in examination of the liver, gall bladder and bile ducts is a useful thesis with which roentgenologists should be familiar. Much of the subject is already familiar to American investigators through the works of Cole, Niles, Case, Pilcher (J. T.), Pacini, Carman, Pfahler, George, Gerber and others. The book is concluded with a section that deals on historical notes and abstracts from the literature of the radiography of the liver, gall-bladder and bile-ducts. This section is important to the investigator who desires a review of the work done in this field. The book is good and might well be included in the x-ray library.

KNOX, ROBERT: "Radiography and Radio-Therapeutics. Part I, Radiography." Published by the Macmillan Company, New York, and A. & C. Black, Ltd., London, 1921.

THIS work, in two volumes, the first dealing with radiography and the second with radiotherapeutics, is too well known to require lengthy comment. For a general treatise on radiography and radiotherapeutics it would be difficult to excel these two volumes. The bibliographic references are few. It is an indispensable set for the roentgenologist.

LAW, FREDERICK M.: "Mastoids Roentgenologically Considered." (Annals of Roentgenology, Volume I.) Published by Paul B. Hoeber, New York, 1921.

UNDER the general editorship of Doctor Case, Doctor Law presents in the "Annals of Roentgenology" the first volume dealing with roentgenology in mastoid diseases. The general scope of the book includes a discussion of the technique for the production of mastoid plates. There is included an atlas giving photographic prints of master roentgenograms that are most skillfully reproduced. These actual photographs present practically all of the pathologic conditions observed by the roentgenologist. Each master roentgenogram is accompanied with an interpretation (in three languages, English, French, and Spanish) which affords not only a means for the proper study of mastoid plates but also a means for reporting the pathology visualized. Roentgenologists who have much to do with surgeons interested in mastoid trouble should be equipped with this preeminently masterful atlas.

MCCOY, JAMES DAVID: "Dental and Oral Radiography. —A Textbook for Students and Practitioners of Dentistry." Second Edition, 1918. Published by C. V. Mosby Company, St. Louis, Mo.

MCCOY's book is quite similar to Ivy's, which it resembles in many respects. In the light of present day dental x-ray technique it is doubtful if this book, like Ivy's, can be of great value to the roentgenologist.

MACKENZIE, WILLIAM COLIN: "The Action of Muscles, including Muscle Rest and Muscle Re-Education." Published by Paul B. Hoeber, New York, 1918.

MACKENZIE's "Action of Muscles" is not an x-ray publication; but it contains the principles of muscle action, a full knowledge of which is imperative for the roentgenologist who would interpret the significance of deformities attending fractures. In many instances it is not necessary that the surgeon depend upon the x-ray alone for the diagnosis of fracture; but the roentgenogram interpreted in the light of deformity due to muscle action affords the surgeon invaluable information that is not otherwise gained from the ex-

amination. Modern roentgenologists should become thoroughly familiar with Mackenzie's book.

OVEREND, WALKER: "Radiography of the Chest, Vol. I, Pulmonary Tuberculosis." Published by C. V. Mosby Company, St. Louis, Mo., 1920.

THERE is described first an unpathological chest as it appears on the x-ray plate. The technique in producing the plate is discussed, and agrees, in general, with that usually advocated by workers in this country. The author then ventures a classification of pulmonary tuberculosis, which condition he divides into the following types: I. Tuberculous disease of the bronchial glands. II. Disseminated nodular phthisis. III. Disseminated nodal phthisis. IV. Bronchopneumonic pseudo-lobar tuberculosis. V. Chronic attenuated phthisis. V. Fibroid phthisis. VII. Pneumonic phthisis. VIII. Miliary tuberculosis. Each class is discussed, x-ray reproductions are given and case histories included in order the better to make for a clear conception of the entity. A chapter is devoted to a study of the complications of pulmonary tuberculosis; and the author concludes the book with a discussion of the radiographic diagnosis. An interesting paragraph is that entitled Pulmonary Tuberculosis in the Great War. It reads:

"Both the French and Italian authorities have attacked the serious problem of the tuberculous soldier in a comprehensive and satisfactory manner. The latter—fortunately able to take some time in preparation—installed diagnostic centres (*Reperti di accertamento diagnostico*) to investigate all cases. Caccini (MEDICAL RECORD, 1918) describes that established at Rome. The Italian medical boards employed rigorous methods for the purpose of admitting men into the armies. They rightly rejected those with a history of past pleurisy, including interlobitis, with pleuritic thickenings and adhesions, the relics of past disease. At first it was thought that such men might be utilized in the auxiliary services; but inasmuch as they are only able to give a minimum of work, and are liable, under the periods of excessive mental and bodily strain imposed by military necessity, to recrudescence or to new manifestations, it was considered advisable to reject them, except under special conditions of urgency. The logical deduction is that recruits after admission must be considered free from tubercle, and that all cases of tuberculosis arising subsequently must be regarded as caused by the vicissitudes and by the fatigue of warfare. The x-rays were preferred to tuberculin, and radiography fortunately took precedence over radioscopy. Stereoscopic pictures were taken in the sitting position, with the tube behind. The data were divided into (a) positive, and (b) presumptive. Positive evidence was arranged in four categories, viz., (1) tubercle bacilli +; (2) larynx +; (3) Tbc.—; signs +; X-ray +; (4) Tbc.—; signs —; X-ray +. Examination of the larynx is indispensable, since tuberculosis may be active in this situation and clinically latent in the lung. The radio-signs in the fourth category include bronchopneumonia and pleurisy, followed to their possible consequences; evidence, however, which should be considered presumptive, or in which a final decision should be postponed (Author). The presumptive evidence falls under three sections, (1) Tbc.—; signs +; symptoms —; X-ray +; (2) Tbc.—; signs —; symptoms +; X-ray +; and (3) Tbc.—; signs —; symptoms —; X-ray —. Under section 3 the X-ray signs of peribronchitis and bronchoadenitis are included; signs which may be inconclusive and not necessarily tuberculous (Author). Soldiers exhibiting presumptive evidence were given 4-12 months' leave and then re-examined. Those with minimal signs of presumptive proof were detached for sedentary service. The French Government also established a probation centre for each army (*centre du triage*), and certain of the results have already been published. The examinees consisted of soldiers who had undergone military service and had been subsequently sent back on account of obvious or presumptive tuberculosis. Emile Sergent and Delamoure, of the Paris centre, reviewed 600 cases admitted into hospital for further observation (*Journal de Médecine*, 1916). After complete examination (repeated

clinical, radioscopical and radiographical, investigation of sputum, and tuberculin reactions, temperature charts, blood pressure and pulse), 14 per cent. were found to be nontuberculous. Among these were cases of simple anaemia, emaciation, dyspepsia, of mitral disease, bronchitis, and emphysema. About 5 per cent. exhibited nasal lesions, with emaciation, anaemia, cough, the absence of pyrexia, of increased vocal vibrations, and of fixed adventitious sounds, with the possession of normal arterial tension. One had a foreign body in the lung, another a hydatid cyst. Many cases of nasal disease, including ethmoiditis, antral disease, hypertrophy of turbinates, the presence of spurs and deflections of the septum, are accompanied by a chronic coryza which gradually spreads downwards, leading to granular pharyngitis and bronchitis. There was a bacillary sputum in 15 per cent. which was confirmed by physical and radioscopic examination. Occasionally the latter showed intrapulmonary foci and cavities which the stethoscope was unable to disclose on account of their central and deep situation, or on account of accompanying bronchitis and thickened pleura. In 70 per cent. of the suspects the changes were apical, and in about 50 per cent. tuberculosis was active. The presence of parenchymatous apical changes was shown by dullness on percussion, increased vocal vibrations, crepitations, haemoptysis; the apical opacity being unchanged by cough, and being accompanied on the plate by the presence of striae and small foci. Pleural adhesions were shown by dullness on percussion, diminished tactile fremitus, pleural friction sounds, diffuse opacity with some illumination on cough. Sergeant also gives two signs in addition, viz., inequality of pupils (affected side usually dilated) and supraclavicular adenitis due to the pleural affection. The various items of the pleural syndrome are far from being always contemporaneous, and their duration is as variable as their frequency. 'Les frottements sont très précoces et très fugaces; ils traduisent la présence d'exsudats perméables aux rayons X et caractérisent la période initiale, purement stéthacoustique de la pleurite apicale . . . les voiles qui résultent de l'organisation des adhérences conjonctives sont plus tardifs et plus persistants; ils caractérisent la phase terminale, essentiellement radiologique, de la symphyse du sommet.' These statements lack anatomical verification. Delherm and Kindberg (*Journal de Radiologie et d'Electrologie*, 1917), made observations on one thousand cases at a probation centre in France, but their results are scarcely reliable, since they considered that it is necessary in every case to place in evidence the bacilli of tubercle, and by the fact that radioscopy alone seems to have been employed."

The bibliography and books of reference are quite general and accepted as standard in this country. The volume forms a creditable addition to the literature of chest roentgenography. It represents the European viewpoint and contains much that deserves commendation.

PRINCE, NORMAN C.: "Roentgen Technic (Diagnostic)." Published by C. V. Mosby Company, St. Louis, Mo., 1917.

For general x-ray technique, more especially for the posturing in x-ray exposure, this small volume is quite useful. If the roentgenologist's library is supplied with Hirsch's "Principles and Practice of Roentgenological Technique" the necessity for Prince's book is entirely precluded.

RAPER, HOWARD RILEY: "Elementary and Dental Radiography." Second Edition, 1913. Published by Consolidated Dental Mfg. Company, New York, and Claudius Ash, Sons and Company, Ltd., London.

RAPER's "Elementary and Dental Radiography" appears to have become the standard volume in connection with dental roentgenology. The illustrations are fair and plentiful. The section dealing on apparatus and technique is not entirely modern. Much that appears in this section has been superseded by more recent methods. The book should be included in every x-ray library.

SCHÜLLER, ARTHUR, and STOCKING, FRED F.: "Roentgen Diagnosis of Diseases of the Head." Published by C. V. Mosby Company, St. Louis, Mo., 1918.

THERE is no other book in English that deals with

diseases of the skull Schüller's book contains an exceptionally great amount of information. It presents many references, some of which are misquoted, making for great inconvenience to the roentgenologist interested in studying this subject. The reproductions of the x-ray plates are relatively few and not exceptionally good. Resort is had to sketches used to bring out the more important points of the roentgenogram. The book is useful and might well be included in the library of x-rayists.

SHENTON, EDWARD W. H.: "Disease in Bone and its Detection by the X-Rays." Published by Macmillan and Company, Ltd., St. Martin's Street, London, 1911.

This short monograph is delightfully presented and expounds the principles of the x-ray diagnosis of bone diseases in a manner that is forceful and authoritative. Every roentgenologist should read and practically memorize this exquisite and small volume.

THOMA, KURT H.: "Oral Abscesses." Published by Ritter and Company, Boston, Mass., 1916.

The roentgenologist interested in dental x-ray should be equipped with Thoma's "Oral Abscesses." This book is very general in scope but it provides some good reproductions of dental conditions as revealed by the x-rays, and in addition, it indicates certain secondary complications for which the roentgenologist should be in search of when obscure symptoms present that might be attributed to focal infection. The bibliography at the end of this book is rather general. It contains some references that are valuable to the specialist in dental work.

THOMA, KURT H.: "Oral Roentgenology.—A Roentgen Study of the Anatomy and Pathology of the Oral Cavity." Published by Ritter and Company, Boston, Mass., 1917.

In addition to the preceding volume the roentgenologist should be supplied with this atlas of oral roentgenology. It has excellent reproductions. It should be included in the library.

TOUSEY, SINCLAIR: "Roentgenographic Diagnosis of Dental Infection in Systemic Diseases." Published by Paul B. Hoeber, New York, 1916.

This is one of the earliest books that appeared in connection with the application of x-ray to the study of dental infection. The roentgenologist should have a reading knowledge of this book.

WENDELL, LEHMAN: "Systematic Development of X-Ray Plates and Films." Published by C. V. Mosby and Company, St. Louis, Mo., 1919.

EMPHASIS is laid on the important relations of photographic principles to roentgenology. The author briefly describes the functions and basic methods of development and fixation. He discusses the three methods commonly employed in development, namely, visual inspection, factorial, and tank or stand method, the latter, according to the author, being the most efficient. Reproductions of illustrations showing the effects of over, under and normal exposure, and showing also over, under and normal development are included. A chapter on the making of lantern slides concludes the book. This volume is useful and should prove of value to technicians who desire a compend dealing with x-ray photography.

WHITE, J. RENFREW: "Chronic Traumatic Osteomyelitis—Its Pathology and Treatment." Published by Paul B. Hoeber, New York, 1919.

WHITE's book is not essentially an x-ray one. The subject of osteomyelitis is extremely important to the roentgenologist and surgeon alike. The roentgenologist should be informed of the surgical aspect of osteomyelitis, of its pathology and associated phenomena. Much of White's book has been quoted verbatim in some of the articles in this series. It is important that the x-rayist procure a copy of this volume for ready reference in the more diligent interpretation of osteomyelitic changes.

UNITED STATES ARMY X-RAY MANUAL. (Authorized by the Surgeon-General of the Army. Prepared under the Direction of the Division of Roentgenology.) Published by Paul B. Hoeber, New York, 1918.

This manual is well known to doctors who have served in the United States Army, and to many others. Each section was prepared by a specialist. The book is authoritative. It deals with x-ray physics, with standard positions, with localization and with a brief yet

comprehensive discussion of important diagnoses in bones and joints, sinuses, teeth, thoracic viscera, urinary tract and gastrointestinal tract. There are some pages devoted to x-ray therapy, though this section of the book is quite scant. It is the most valuable book for roentgenologists.

ELEMENTARY PHOTOGRAPHIC CHEMISTRY. Published by Eastman Kodak Company, Rochester, N. Y., 1920. THERE is no necessity for discussing the value of a book on photographic chemistry when prepared under the expert direction of pioneer workers in photography. This book should be especially sought by those who are interested in developing a maximum efficiency in the photographic technique of the x-ray investigation.

X-RAYS. Published by Eastman Kodak Company, Rochester, N. Y., 1921.

THERE is much in this pamphlet of extreme value to the roentgenologist. This book is easily procured and well worth reading.

The above list does not exhaust all x-ray publications. It provides only a working library for the roentgenologist who is desirous of expanding his general store of x-ray information. In addition to these books the *Journal of the American Roentgen Ray Society* and the *American Journal of Electrotherapeutics and Radiology* should be added to every station. There are other periodicals that deal from time to time with x-ray topics.

Speaking generally, the roentgenologist should become familiar with the writings of the following contributors to x-ray literature:

Ashbury, Howard E.	Holmes, G. W.
Bassler, Anthony	Huntington, Philip W.
Baetjer, F. H.	Imboden, H. M.
Beck, Emil	Jaches, Leopold
Boggs, R. H.	Johnston, George C.
Borzell, F. F.	Law, Fred M.
Bowen, David R.	Leonard, R. D. (Deceased)
Brown, Percy	LeWald, L. T.
Carman, R. D.	MacKee, G. M.
Case, James T.	Manges, Willis F.
Childs, Samuel B.	Martin, J. M.
Christie, A. C.	Merritt, Edwin A.
Cole, Albert M.	Mick, W. H.
Cole, Lewis G.	Pacini, A. J.
Coolidge, W. D.	Pancoast, H. K.
Crane, A. W.	Pfahler, Geo. E.
Darling, Byron C.	Pfender, Chas. A.
Duane, William	Pirie, A. H.
Dunham, Kennon	Potter, Hollis E.
Edwards, H. Threlkeld	Quimby, A. J.
Eisen, Paul	Reu, Leonard
Evans, William A.	Ruggles, Howard E.
George, A. W.	Shearer, John S.
Goin, L. S.	Skinner, Ed. H.
Gorsline, C. S.	Stewart, W. H.
Gray, Alfred L.	Tousey, Sinclair
Grier, G. W.	Tyler, A. F.
Groover, Thos. A.	Waters, Chas. A.
Hickey, P. M.	Watkins, Wm. W.

Pallidus Syndrome.—The syndrome due to lesions of the globus pallidus is summed up by Monier-Vinard and Dalsace as follows: A man of sixty presented a pseudo-bulbar syndrome characterized by dysarthria, dysphagia, and spasmodic crying and laughter. There was a tendency of all attitudes, whether spontaneous or induced, to persist indefinitely. Automatic and associated movements were almost abolished. This automatic akinesia agreed throughout with that of Parkinson's disease, contrasting sharply with the freedom of voluntary motion. These motor peculiarities are said by Ramsay Hunt to indicate a lesion definitely limited to the globus pallidus.—*Gazette des Hôpitaux*.

Medicolegal Notes.

Necessity for Operation on Claimant for Compensation in Industrial Commission's Discretion.—The question whether an applicant for compensation under a workmen's compensation act is debarred from compensation because of his refusal to submit to an operation comes before the courts from time to time. A recent case in Illinois was one where the injury resulted in hernia. The Illinois act vests the Industrial Commission with the right to suspend the compensation of an injured employee if he "shall refuse to submit to such . . . surgical treatment as is reasonably essential to promote his recovery." The Illinois Supreme Court holds that whether the operation is reasonably essential is for the Industrial Commission to determine, based up the evidence submitted to it, and it would only be in a case where the commission had acted unreasonably or abused its discretion that the court could interfere with its finding. The Illinois Supreme Court in *Joliet Motor Co. v. Industrial Board*, 280 Ill., 148, 117 N. E. 423, held that where the evidence as to a claim for total loss of sight of an eye showed that such loss was caused by a cataract of slow growth, and that an operation could be performed which would cause little or no pain to the employee, and which would not endanger his life and would probably restore his sight, the Industrial Commission should not award compensation for total loss of sight of the eye, even though it could not compel the employee to undergo an operation. Of course the question to be decided is not that of compelling a party to submit to an operation. As was said in *Donnelly v. Baird & Co.*, 1 B. W. C. 95: "The question is whether a party who declines to undergo what would be described by experts as a reasonable and safe operation is to be considered as a sufferer from the effect of an injury received in the course of his employment, or whether his suffering and subsequent inability to work at his trade ought not to be attributed to his voluntary action in declining to avail himself of reasonable surgical treatment. If in such a case the sufferer, either from defect of moral courage or because he is content with a disabled hand and is willing to live on the pittance which he is receiving under the Compensation Act, refuses to be operated upon, I should have no difficulty in holding that his continued inability to work at his trade was the result of his refusal of remedial treatment and that he was not entitled to further compensation." The court cited to the same effect *Walsh v. Locke & Co.*, 7 W. B. C. 117; *Kricinovich v. American Car & Foundry Co.*, 192 Mich. 687, 159 N. W. 362; *Lesh v. Illinois Steel Co.*, 163 Wis. 124, 137 N. W. 539; *Enterprise Fence & Foundry Co. v. Majors* (Ind. App.) 121 N. E. 6. The court said: "Naturally each case must depend largely upon its special facts. The hernia here was caused by the accident, but it appears that an injury of this kind is not recovered from in the ordinary process of healing by allowing nature to take the ordinary course, as is the case with many wounds. On the facts as found in this record we think the findings of the Industrial Commission suspending the award, as stated above, were justified, and the courts are bound by the commission's finding." Judgment of the circuit court setting aside the award was therefore reversed and the commission's finding confirmed. It appeared from the record referred to by the court that the operation proposed involved "cutting through the skin, the subcutaneous tissue, the covering of the muscles, making a slit about 2½ inches long, an opening to be made reaching to the peritoneum or tunica vaginalis, depending upon the type of hernia, and involving some further manipulation of parts and surgical work in correcting the condition caused by the hernia."—*D. W. Rosenthal & Co. v. Industrial Commission* (Ill.) 129 N. E. 176.

Obesity Following Epidemic Encephalitis.—Livet calls attention to this sequence. The weight put on may reach 30 pounds. One patient showed a synchronous amenorrhea, which suggests that in this febrile condition the integrity of the endocrine glands is impaired. The hypophysis is the only one in which we might anticipate such implication.—*Gazette des Hôpitaux*.

MEDICAL RECORD.

A Weekly Journal of Medicine and Surgery.

THOMAS L. STEDMAN, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 FIFTH AVENUE.

See fourth page following reading matter for Rates of Subscription and Information for Contributors and Subscribers.

New York, June 25, 1921.

MR. VOLSTEAD HEARS SOMETHING.

In his baccalaureate sermon addressed to the graduating classes of Harvard University on Sunday of this week, President Lowell insisted on clear thinking as the crying need of the day. To meet the urgent problems of the day, he said, we need not more organization or more machinery, but more personal thought, clear, far reaching, profound, and wide-spread as possible, for "in the multitude of the wise is the welfare of the world." It is a great pity that these words could not have been addressed to and taken to heart by the author of the so-called Volstead act, for he sadly lacks clear thinking. Not long ago he was quoted in the newspapers as saying that the medical profession was entirely satisfied with his restrictions on their use of alcohol, for only one physician had appeared before the congressional committee protesting against the provisions of the proposed new Volstead law. The medical profession simply, as is so often the case with it until too late, had not yet waked up. It is waking up now and Dr. Davin of New York who attacked the fanatics of the committee single-handed is probably beginning to feel less lonesome. Individual physicians do not yet appear to have overcome their shrinking modesty sufficiently to utter public protests, the only ones coming to our notice being eight New York physicians who wrote a letter to the Association *Journal* calling attention to the iniquities of the Volstead Act, but the American Therapeutic Society at its annual meeting in Washington protested vigorously against the intolerable restrictions on medical practice imposed by this law, and since then a great many local and county societies have passed resolutions of the same tenor.

An attempt was made to get the House of Delegates at the meeting of the American Medical Association to repeat its comedy of four years ago in declaring that there was no scientific basis for the therapeutic use of alcohol. More wisdom prevailed at this meeting, however, than at that of 1917, and the declaration was not reaffirmed but the question was referred to the Committee on Scientific Research, where it properly belongs and where it will rest for a year. The MEDICAL RECORD

has voiced its protest against this and other outrageous attempts by ignorant laymen to regulate medical practice, but the medical press in general, with a few exceptions, has been shy of expressing disapproval of this oppressive law. However, the American Medical Editors' Association has now come out with a set of preambles and resolutions protesting against "further undue regulation of therapeutic procedure" and calling for a revision of the existing statutes. The resolutions, we regret to say are wordy and weak, and the protest should be against not only "further" but also present regulation of therapeutic procedure, and since every such regulation by lay enactment, is "undue," it is unfortunate that this qualification should have been inserted. However, it is well that the Association has put itself on record, even if feebly, and it is probable the resolutions were intended to be more forceful than they are.

But it is not only medical men and their patients who suffer from this meddlesomeness of the W. C. T. U. and its congressional subservients; chemists and manufacturers are also beginning to wake up and to find that the Volstead act is destined to work irreparable injury to the chemical and other industries of the country if it is allowed to stand in its present or proposed shape.

We trust Mr. Volstead has learned by this time that the medical profession is not unanimously in favor of submitting to his prejudices in regard to the practice of therapeutics, although that would probably not trouble him, for "doctors" don't count politically, at least most politicians still think so; but now that the chemical and manufacturing industries are aroused we have some hope of reason penetrating to the committee room. If we are not to be allowed to help our patients by giving them alcohol when they need it, we shall at least be thankful if the drug manufacturers are permitted to get enough grain alcohol for use in making tinctures, fluid extracts, and other pharmaceutical preparations. Perhaps some day when the author of this outrageous bill rests in a teetotaler's grave, the country will wake to the fact that temperance can be promoted without killing the sick or ruining our manufactures.

THE CIRCULATORY SYSTEM IN DIPHTHERIA.

In diphtheria in children the morbid changes taking place in the heart are usually intimated only by the pulse, as myocarditis undergoes a latent evolution in the young. Careful auscultation will usually reveal nothing abnormal and this form of latent myocarditis is quite similar to that met with in children with typhoid fever. Being unsuspected it may be the cause of sudden death. In some cases, however, some disturbances may be detected. By palpation of the precordial area the hand only perceives a slight undulation of the thoracic wall or a few irregular cardiac shocks. The apex, when it can be perceived, is low and carried outwardly, while percussion may reveal

an acute dilatation of the cardiac cavities coinciding with an increase in the size of the liver. There is an arrhythmia and the heart sounds are distant and dull. When cardiac paresis is accompanied by albuminuria the work of the heart is made more difficult; there is a gallop rhythm with a superadded murmur extending far into the diastole, while a soft systolic blow at the apex is heard, due to dilatation of the ventricles rather than to valvular changes. In other cases there is more particularly a weak first sound at the apex—a bad prognostic sign.

Very often these data are not found, in which cases the state of the pulse becomes of first importance. Various changes have been described in convalescence from diphtheria, but these do not have an equal clinical value. They are acceleration, slowness, irregularity, and weakness of the pulse. For some observers acceleration with weakness is one of the best signs of diphtheritic intoxication. It is met with at the onset of the disease, with or without a rise of temperature, but subsides rather quickly after serum has been injected. This symptom has such great semeiological value that when it persists after serotherapy it can be regarded as one of the best indications of a serious form of the disease. If after having become normal the tachycardia reappears, although the temperature remains normal, it is a certain indication that there is an offensive return of the disease. It generally coincides with the development of paralytic phenomena and one of the early symptoms of bulbar accidents is a pulse of 160 beats or more.

An increased frequency of the pulse and a low blood-pressure are the result of diphtheritic intoxication and the frequency is in direct ratio to the degree of the intoxication. Therefore the old maxim is as true to-day as before the use of serum that death is the rule when the pulse goes above 150. That is to say, that although the tachycardia is practically constant in untreated cases, it becomes a more serious matter when it continues in convalescence after serum has been used.

A slow pulse is rare in diphtheria and its prognostic value is great. Some have maintained that this postdiphtheritic symptom is a good sign, while others equally competent uphold that bradycardia during convalescence from diphtheria is often accompanied by cardiac disturbances, dyspnea, and distress; syncope and death almost invariably occur in from three to four days. Less than sixty pulsations per minute in a child should be regarded as a sign of serious cardiac disturbance.

A weak accelerated pulse indicates an advanced degree of intoxication and a bad prognosis as it shows the unstable equilibrium of the primordial functions of the vegetative life of these profoundly intoxicated subjects, as well as a state of depression of the entire nervous system. The slightest jar or emotion are enough to induce fatal syncope.

The subject of the blood-pressure from the viewpoint of the prognosis is interesting and when it falls to 60 or 65 mm. Hg. in children the prognosis is nearly always fatal. The diphtheritic toxin exercises an unfortunate influence on the circulation through paralysis of the bulbar center of the vasomotor nerves resulting in tachycardia, irregular pulsation, and a fall in the blood-pressure. Numerous studies carried out in the past by Kolossova, Durand-Viel, A. Denis, not to mention others, have shown that only the more serious forms of diphtheria give rise to changes in the blood-pressure, the pulse then becoming soft and depressible at the onset of the disease, or during convalescence. When the radial pulse cannot be felt these changes in the blood-pressure almost invariably indicate an extremely serious prognosis.

TOXIC SECRETIONS OF WORMS.

THE prevalent view of intestinal helminthiasis up to within comparatively recent times was that, though unpleasant it was seldom dangerous, barring occasional accidents such as perforation or obstruction of the bowel. We have learned, however, that systemic disease and even death may result from the presence of worms in the intestine. Writing in *La Presse Médicale* of April 9, 1921, xxix, 29, Rouillard states that worms may injure the host in several ways—traumatic, reflex, or toxic. Formerly the latter activity was but little surmised, but of late our knowledge of it has increased so rapidly that we now place it at the head of the noxae of verminous origin. Phenomena due purely to exsanguination are not reckoned under toxemia, although often due to that cause, and the two types readily coexist. In Japan a small trematode worm, the *Clonorchis sinensis* is notorious for its toxic manifestations. It attacks through its toxins the muscles and causes a form of progressive muscular atrophy. Several worms cause urticaria and pruritus through mildly toxic secretions. Those who handle or dissect ascarides are sometimes subject to inflammation and itching of the fingers, conjunctivitis, and coryza or pharyngitis. That the peculiar blood formulæ in worm diseases are not due to secondary anemia from hemorrhage is well seen in the fact that worms which do not induce hemorrhage at all can cause notable blood alterations. Conversely the bothriocephalus which may cause intense secondary anemia does not cause eosinophilia, although nearly every other intestinal worm does produce more or less of this blood picture, so that the blood find of eosinophilia at once suggests some form of helminthiasis. Various worms may cause temperature rise and there is a clinical condition known as "lumbricoid typhoid." The bothriocephalus mentioned above causes at times a profound cachexia in which numerous toxic phenomena are recognizable. The ancylostoma can stunt children and cause women to abort.

But in order to make out a case for a toxic mechanism it is of course imperative to isolate

and study the toxic principle and set up diseases in laboratory animals. Among products specially studied have been the extract of the cephalic glands of the ancylostoma, the secretions of ascarides, and the excreta and ova of various other worms. In a large body of data accumulated some discordant results appear, so that only the more striking and constant finds can be given. The author mentions no fixed principle isolated in any of these experiments and the identity rests chiefly on the humoral reactions provoked. The toxic phenomena produced in small laboratory animals were somewhat unconvincing so far as any specificity was concerned, while in the dog the action was not marked save that a secretion or fluid obtained from a species of ascaris proved to be a powerful cardiac poison. Moreover it appeared that animals can rapidly acquire tolerance to these poisons. In fact a single injection of some of these substances causes immunity to further exhibition of the same substance. In concluding, the author doubts the existence of specific toxins, stating that the results obtained are those common to the injection of foreign protein in general. To this must be noted in the clinic the superaddition of microbial infections through the portals established by the worms. Despite the immunity which has followed injections in some cases there is also the converse tendency to sensitize and produce anaphylaxis. The most characteristic evidence of a toxic action in the clinic is the production of eosinophilia.

TREATMENT OF SLEEPING SICKNESS.

TRUE sleeping sickness, trypanosomiasis, is believed to be incurable, the only way to deal with the disease being to put into force drastic preventive measures. However, at a meeting of the Royal Society of Tropical Medicine and Hygiene, held in London on May 20, a paper was read by Dr. Claude H. Marshall on "A New Method of Treatment of Trypanosomiasis," embodying the results given in an article by himself and Dr. Vasallo and published in the *British Medical Journal* of May 28. A previous report on the treatment of sleeping sickness by combined intravenous and intrathecal injections of salvarsanized serum appeared in the same journal, May 22, 1920. Doctor Marshall and his colleague have treated 56 cases, the majority of them for a year or less. Eight of these are dead, of six there are no records, while all the remaining cases are doing well. The drugs tried so far have been neokharsivan, which has been employed most extensively, and atoxyl to a less extent, but all the cases referred to in the paper by Marshall and Vasallo were treated mainly by neokharsivan. It is claimed that the treatment is curative, and the investigators hold that this curative effect results from the formation and action of some form of trypanolysin. Moreover, if the theories of these authors are correct, there would appear to be no reason why animal serum should not be used for treatment, why some degree of prophylaxis and immunity to trypanosomiasis should not be obtained, and why early diagnosis should not be effected by

some form of complement fixation test. Although the president of the Royal Tropical Society, Prof. W. J. R. Simpson, expressed himself favorably with regard to the means of treatment and Prof. W. D. Halliburton congratulated the investigators in that they had found a material which was fatal to the parasite but not fatal to the host, the method was subjected to destructive criticism by two very distinguished exponents of tropical medicine, Dr. P. Manson-Bahr and Dr. G. C. Low. The value of the treatment rests on its action on the cerebrospinal fluid, and Bahr doubted whether the invasion of the cerebrospinal fluid was necessary to produce sleeping sickness. He held that it was not. Low did not think that a case could be regarded as cured until after a period of at least three years. It was therefore impossible to regard Doctor Marshall's cases as cured after only one year. However, the sense of the meeting was that facilities should be afforded for a thorough testing of the treatment.

News of the Week.

Public Health Committee of the New York Academy of Medicine.—At the meeting of the Public Health Committee on June 13, the medical aspects of workmen's compensation were discussed in connection with a report on the subject made for the committee by Dr. Ransom S. Hooker. The report points out that the compensation law of this State, though liberal, is yet deficient, particularly in its medical provisions, and that there has been no supervision of the medical and surgical care given to the injured workman. The right of the free choice of physician is denied to him under the law, and therefore it devolves upon the State authority to insure to him proper medical treatment. The report points out that the medical officers of the Labor Department are on full-time duty and that their compensation is inadequate for the task expected of them.

A second matter considered by the committee was the request from the health authorities of one of the large cities of the country asking for an opinion as to the type of ventilation to be installed in the proposed new schools of that city. The opinion of the committee was in favor of open air window ventilation. The studies made some time ago by the New York State Commission bear out the position taken by the committee.

Bubonic Plague in Tampico.—Thirty-seven deaths from bubonic plague occurred in Tampico during May, according to the bill of health issued by the Cuban Consul at Tampico to the American tanker *Albert E. Watts* which arrived in the port of New York on June 11. One death a day from this disease was reported during the first week in June.

American Tuberculosis Association Adopts Resolutions.—At its annual meeting in New York City, June 15-17, this organization adopted resolutions calling on the United States Public Health Service to see that examiners specially trained for the detection of tuberculosis be stationed at all the ports of debarkation, and requesting the steamship companies to use greater care in accepting for passage immigrants coming from the regions of

Europe which are particularly infected with tuberculosis. Other resolutions expressed appreciation of the effort of the American Legion leaders to correct the defects in legislation regarding the rehabilitation of ex-service men. It was recommended that immediate material reduction be made in cases of those who refuse to make proper use of the facilities provided for their benefit, and that appointment of officers to care for tuberculous ex-service men be made for the welfare of the men and not out of regard to personal influence. Memorial resolutions on the death of Major-General William C. Gorgas, ex-Surgeon General of the United States Army, were also adopted.

Beer for Medicine Regulations Ready.—New beer regulations, legalizing the manufacture and sale to the public of "medicinal" malt liquors were ready for the signature of Revenue Commissioner Blair on June 14. It is officially declared that the threats of Representative Volstead to rush his anti-beer bill through Congress before the Government had time to put into effect rules authorizing the sale of beer will not deter the Treasury or cause further delay. It is expected that the new rules will be signed immediately. Dr. John E. Teeple, chairman of the New York Section of the American Chemical Society has announced that the Rules Committee is going to give the scientists of this country an opportunity to expose the so-called anti-beer bill in its true colors. The measure, he says, is nothing but a deliberate attack on American industry, hypocritically worded and advertised as a bill to prevent the use of beer as medicine. The bill does not mention the word beer, but assumes to restrict the use of chemicals, drugs, and pharmaceutical preparations recognized by all physicians as necessary for the treatment of disease.

Dogs for Experimental Purposes Well Treated.—A committee appointed by the Indianapolis Humane Society to investigate alleged cruel treatment of dogs in vivisection at the Indiana University School of Medicine, reports that on a recent unannounced visit to the school of medicine it was found that the dogs were being humanely treated.

Peking Union Medical College.—Plans are announced for the dedication of the new buildings of the Peking Union Medical College, erected by the China Medical Board of the Rockefeller Foundation. The ceremonies will fill the week from September 15 to September 22 and will include an international medical conference to which scientists from America and European countries as well as from the Far East have been invited. At the time will also occur the inauguration of the director of the college, Dr. Henry S. Houghton, and regular sessions of the institution's board of trustees, which is composed of representatives of the Rockefeller Foundation and of six missionary societies which had maintained an earlier medical college in Peking, will also begin then.

To'io Hospital Lauded.—At a benefit performance of the Japanese play "The Forty-seven Ronins" presented in Tokio, on June 11 for St. Luke's International Hospital, Viscount Eiichi Shibusawa, in an address, acknowledged the high service rendered in the cause of medicine in Japan by Dr. R. B. Teusler of Virginia. He referred to the hospital as an international institution, bound to promote

friendly relations between the United States and Japan, and said that men like Dr. Teusler would do much "to remove misunderstandings between the two countries and to establish friendship on a firm basis."

Rural West Virginia Needs Doctors.—According to the authorities of the School of Medicine of the University of West Virginia there is a pressing demand for physicians who will practise in the rural communities of that State. They state that Summersville, the county seat of Nicholas County, does not have a doctor, and Clay County has only one to look after the people living in its 332 square miles. In some of the other counties many people live from fifteen to twenty miles from the nearest physician, and in some of the mountain counties it is almost impossible to get doctors to make visits into the country districts.

Base Hospital Burns.—The base hospital at Fort Niagara and seven connecting buildings were burned on the morning of June 11. The loss, including hospital equipment, is estimated at \$200,000.

New Hospital for St. Louis.—The Imperial Council, Ancient Arabic Order, Nobles of the Mystic Shrine, announce that they are prepared to establish a hospital for crippled children of North America in St. Louis. A site has been purchased for \$150,000.

Home for Blind Children.—The Catholic Archdiocese of New York has purchased two four-story brown stone houses at 221 and 223 East Seventy-ninth Street for \$65,000, to be used as a home for blind children.

Sir Robert Jones of the University of Liverpool received the honorary degree of Doctor of Science from Smith College, at its commencement exercises on June 14.

Madame Marie Curie was made an honorary member of the Medical Women's National Association, at its meeting in Boston, June 11.

Dr. Crawford C. McCullough of Fort William, Ontario, was elected president of the International Association of Rotary Clubs at its annual session held in Edinburgh, Scotland, during the week of June 13.

Dr. Charles H. Mayo of Rochester, Minn., was made a Doctor of Laws at the commencement exercises of the Northwestern University on June 15.

Dr. Hugh Cabot has been appointed dean of the Medical School of the University of Michigan to succeed Dr. Victor C. Vaughan, resigned.

Dr. William T. Jenkins, formerly Health Commissioner of New York City, is seriously ill at the Hahnemann Hospital, New York.

Charitable Gifts and Bequests.—Under the will of Mrs. Ellen V. D. Hazelton of New York the following New York institutions are beneficiaries: New York Society for the Ruptured and Crippled, \$10,000; New York Eye and Ear Infirmary, \$10,000; Brooklyn Home for Consumptives, \$5,000. The residuary estate is to go to the Saratoga Hospital, Saratoga Springs.

By the will of the late Peter T. Hallahan of Philadelphia, the sum of \$1,000 is bequeathed to the St. Vincent's Maternity Hospital.

Commencements.—At the 165th Commencement of the University of Pennsylvania held on June 15

the degree of Doctor of Medicine was conferred upon 118 graduates, six of whom were women. The degree of Doctor of Public Hygiene was conferred on one graduate. The degree of Doctor of Laws was conferred on Dr. Hobart A. Hare, professor of *Materia Medica* and *Therapeutics* in Jefferson Medical College.

At the commencement of the Woman's Medical College of Pennsylvania held on June 15, the doctorate was conferred upon 16 graduates. The graduation address was delivered by Dr. Walter B. Cannon of Harvard University.

Philadelphia Medical Club.—A dinner and reception were given on June 13 in honor of Dr. W. Blair Bell and Dr. R. G. Rows of London.

New York and New England Association of Railway Surgeons.—The thirty-first annual session of this association will be held at the Hotel McAlpin, New York City, on Saturday, October 29, 1921. Dr. Charles Mayo, will deliver the oration in surgery. The symposium will be "the Surgery of the Stomach and Duodenum." Dr. J. Frank Black of White Plains, N. Y., is president. Dr. Geo. Chaffee, 170 Court Street, Binghamton, N. Y., is corresponding secretary.

Proposed Amalgamation of Medical Schools Opposed.—The General Alumni Association of the University of Virginia, at a special meeting on June 3, adopted resolutions protesting against the consolidation of the Medical College of Virginia with the University of Virginia, recently recommended by the Commission on Medical Education in Virginia. The text of the resolution states "That the General Alumni Association of the University of Virginia hereby expresses its unqualified opposition to the proposed removal to Richmond of the Medical Department of the University as a step opposed to the interests of the State of Virginia, as injurious to the cause of medical education, as destructive to the integrity of the University of Virginia, and as violative of those principles of higher education which, established by Thomas Jefferson, have received the sanction of time and of experience." Dr. Hugh H. Young of Baltimore presided at the meeting.

Obituary Notes.—Dr. WILLIAM J. BURGE of Edgewood, R. I., a graduate of the College of Physicians and Surgeons, New York, in 1853, died on May 28, at the age of ninety years. He was a surgeon in the United States Navy during the Civil War, a member of the Rhode Island Medical Society, and for three years president of the Providence Medical Association.

Dr. FRANK MASON, a graduate of the Ohio State University, died at his home in Milwaukee on May 14.

Dr. SAMUEL TANDLICH, a graduate of New York University Medical College in 1897, died at his home in New York City on May 28.

Dr. JACOB A. FIELDS of Giddings, Texas, died on May 14, at the age of sixty-nine years. He was graduated from the Medical Department of Tulane University in 1875.

Dr. MARTIN J. NEVINGER died at Philadelphia on May 26, at the age of forty-four years, following an operation. He was graduated from Hahnemann Medical College of Philadelphia in the class of 1898.

Dr. GEORGE R. SPRATT died at Coatesville, Pa.,

on May 22, at the age of eighty-two years. He was graduated from the medical department of the University of Pennsylvania in the class of 1864. He was for many years president of the Coatesville Board of Health.

Dr. ALBERT S. BLOUGH, formerly of Elizabethtown, Pa., died at Marietta on May 26 at the age of forty-six years. He was graduated from the Medico-Chirurgical College in the class of 1904.

Dr. JESSE ALBERT BOLIN died at Philadelphia on May 27 at the age of sixty-five years. He was graduated from Jefferson Medical College in the class of 1881. He was at one time physician to the Coroner's Office. He was a member of the Philadelphia County Medical Society and of the Medical Society of the State of Pennsylvania and of the American Medical Association.

Dr. FRANK H. ROWE, a graduate of Miami Medical College, in 1873, died at his home in Cincinnati, on May 4, at the age of seventy-three years.

Dr. FREDERICK WILLIAM WUNDERLICH of Brooklyn, died of pneumonia on May 16, at the age of seventy-nine years. He was graduated from the St. Louis Medical College in 1864. He was a member of the American Medical Association and the New York Academy of Medicine. He was surgeon to St. Peter's Hospital and consulting surgeon to the Wyckoff Heights Hospital.

Dr. JOHN M. KNOTT of Sioux City, Ia., a graduate of George Washington University Department of Medicine in 1870, died of angina pectoris in Los Angeles, Cal., on May 14, at the age of seventy-four years.

Dr. ROBERT ROY BROWNFIELD of Phoenix, Ariz., a graduate of the Medico-Chirurgical College of Kansas City, Mo., in 1903, died from injuries received in an automobile accident on May 1, at the age of forty years. He was president of the Maricopa County Medical Society in 1919.

Dr. J. C. GRAFFIN, formerly of Grass Valley, N. M., died at Shiprock, N. M., on May 5, at the age of fifty-two years. He was a graduate of the New York Homeopathic Medical College and Hospital in 1895.

Dr. ROBERT B. WOODWARD, a graduate of the Cleveland University of Medicine and Surgery in 1867, died suddenly at his home in Somers, Ohio, May 15, at the age of eighty-two years.

Dr. JAMES M. EARLE of Darlington, S. C., died suddenly on May 14, at the age of sixty years. He was graduated from New York University in 1886.

Dr. LAURISTON HARDIN HILL of Germantown, Pa., a graduate of the University College of Medicine, Richmond, Va., died on May 14, at the age of eighty-four years.

Correspondence.

OUR LONDON LETTER.

(From Our Own Correspondent.)

LONDON, May 31, 1921.

Uniformity Required in the Treatment of Tuberculosis Cases.—It is now generally agreed that there is no one way of treating successfully cases of pulmonary tuberculosis. The sanatorium is not sufficient by itself, nor the colony nor the hospital. All these means are necessary if the

disease is to be eliminated or even greatly checked. If, as is the common belief, the chief source of origin of virulent tubercle bacilli is the sputum of those suffering from pulmonary tuberculosis in an advanced stage, it appears obvious that the provision of adequate hospital accommodation and the segregation and control of these advanced cases will ultimately lead to the stamping out of the tubercle bacillus. There is a certain degree of analogy between leprosy and tuberculosis and leprosy was abolished from Europe in the Middle Ages mainly by compulsory segregation. However, it may be taken for granted that for the sake of the community at large, hospital treatment for advanced cases is absolutely indicated as well as for certain cases still amenable to treatment. But when such accommodation has been provided on an adequate scale there is another point which must be borne in mind, that there is a pressing need for greater uniformity with respect to the therapeutic measures carried out. Dr. H. Hyslop Thomson, Medical Officer of Health for Hertfordshire, read a paper on the subject before the Tubercle Group of the Society of Medical Officers of Health, whose meeting was held a short time ago. Thomson emphasized the importance of rest in the treatment of pulmonary tuberculosis, and in his opinion absolute rest in bed must be regarded as the foundation of hospital treatment. The results obtained by prolonged rest in the treatment of tuberculosis of bones and joints are well-known. Many authorities have laid stress on the need for absolute rest in the treatment of tuberculosis of the lungs. Among these Dr. Marcus Paterson has constantly recommended complete immobilization in the treatment of cases of autoinoculation. He holds that such patients should not only be sent to bed but should be treated in every way, with the exception of diet, like a typhoid patient. T. H. Pratt of Boston, writing in the *American Review of Tuberculosis*, 1918, on "The Importance of Prolonged Rest in the Treatment of Pulmonary Tuberculosis," also advocated complete immobilization not only in febrile cases but also for a definite period in non-febrile cases. Thomson's own experience of the hospital treatment of pulmonary tuberculosis during the past few years is that absolute rest in bed is indicated in all cases in which the month temperature reaches 99° F., even if only occasionally, or in which the pulse rate at rest is persistently up to 90° or higher. He draws attention to one significant fact which has occasionally come under his observation, namely, that certain patients who have steadily improved under hospital treatment have relapsed under sanatorium treatment when transferred from one institution to the other. The cause of this is, no doubt, due to autoinoculation following a too rapid introduction to walking exercise. It will be observed that Thomson is in favor of hospital treatment of those whose cases are not hopeless as well as of those very advanced cases who must be segregated for the good of the race. He thinks that the value of hospital treatment as a curative measure in certain types of the disease is of importance as pulmonary tuberculosis is a disease which shows considerable variation in type and in its charac-

ter of onset. Not infrequently the onset is acute with severe constitutional disturbance. In such cases immediate hospital treatment with absolute rest is essential if the progress of the disease is to be arrested. The treatment of pulmonary tuberculosis at the present time appears to have crystallized into hospital treatment, sanatorium treatment, and colony treatment, and it is anticipated that this trinity of methods in wise cooperation will show excellent results.

Report of the London Radium Institute.—That radium as a therapeutic agent is gaining in favor seems certain and in support of this view the annual reports of the medical superintendent of the London Radium Institute Mr. A. E. Hayward Pinch, F. R. C. S., supply convincing proofs. The report issued recently covers the period, January 1 to December 31, 1920. This report differs essentially from any previously published in that an attempt is made to present radium therapy on a rational scientific basis. The principles of treatment set forth are based mainly on methods hitherto employed at the institute, at the same time full consideration has been given to successful methods introduced by other investigators. Operable cases of malignant disease are not treated, except rodent ulcer, save in those instances in which the patient has absolutely refused to submit to operation. The cases dealt with during the year numbered 896, and are summarized as follows: Examined but not treated, 78; recent report not received, 114; received prophylactic treatment only, 38; apparently cured, 133; cured, 28; improved, 336; not improved, 74; abandoned treatment, 62, and died, 33. Altogether 8,131 treatments were administered during the year, of which 4,598 were given free of all charge to necessitous patients and 765 emanation applicators were prepared during the year and distributed to hospitals and medical practitioners throughout the United Kingdom for the treatment of patients. A study of the report goes to show how wide a field of usefulness radium possesses. More than one form of malignant disease may frequently be successfully treated by radium. Among these diseases may be mentioned different varieties of carcinomata, sarcomata, and rodent ulcer. Non-malignant conditions often respond favorably to the exhibition of radium. Of such affections attention may be drawn to the following: Fibromyomata of the uterus, leucocythemia, exophthalmic goiter, tuberculosis, nevi, keloids, leucoplakia, warts, papillomata, various superficial skin lesions, including chronic eczema, psoriasis, pruritus, etc. A report on the Research Department is submitted by Mr. T. C. Mottram, M.B., D.P.H. It is interesting to note, in view of the fact that somewhat obscure fatalities and injuries have been attributed recently to the action of radium and x-rays on those who administer them, that a paper dealing with the blood of the workers at the institute was published in the *Archives of Radiology and Electrotherapy* for December, 1920. In this communication the red cell content was dealt with. In several cases a mild anemia was found, down to 4,150,000 per cubic millimeter for males and 3,300,000 for females. In all these cases the color index was

above the normal. The report is a valuable addition to the literature on radium.

Dangerous Drugs.—A Departmental Committee on the Draft Regulations under the Dangerous Drugs' Act, 1920, whose report was issued on May 26 last, recommended that the manufacture and sale of the specified drugs, morphine, cocaine, ecgonine, and heroine and their respective salts, and medicinal opium, shall be carried on only by persons and in places licensed by the Home Secretary, and that these drugs shall be supplied only to persons provided with a properly signed medical prescription. These drugs should be supplied in packages or bottles plainly marked with the amount of the drug, and their sale must be entered in a special register. Stringent regulations in regard to the signing of prescriptions are recommended.

Rural Sanitation.—The country would seem to be, in the nature of things, the most healthy place in which to live. It should be but all too frequently it is not. Sanitation in many rural areas of Great Britain, the home of good sanitation, is at a low ebb. Refuse and rubbish are left about to pollute the streams and ponds and possibly contaminate the water supply. The water for household use in country cottages is usually obtained from an open well liable to outside contamination and, what is far more serious, it is liable to be polluted by means of the deep privies situated in the garden often near the well or sufficiently near for the excreta to seep through the soil, of course, sometimes carrying the germs of disease, enteric fever, for instance. As a matter of fact, in some rural districts in this country the standard of sanitation is almost the lowest imaginable. It is therefore encouraging to learn that the Women's Village Council Federation, according to an editorial in *National Health*, April, 1921, is taking steps toward reformation of this really deplorable state of affairs. As the editorial in question points out, what effect are such bad housing and sanitary conditions likely to have upon the children brought up amidst them? In these days we are realizing that the earliest impressions gathered along life's way are the ones that count most toward the making of character and the development of efficiency. Can much be expected from the individual whose early life is impressed by crudities which may and do imperil the refinement which surroundings of rural beauty may induce? The town is often healthier than the country on account of its superior sanitation and to some extent better hygienic conditions. The situation is similar in most countries. The rural sanitation in America is probably as bad as in Great Britain. One of the first steps to be taken in the direction of the prevention of disease is to improve the housing accommodation and the sanitary and hygienic conditions in rural districts.

For the Protection of X-ray Workers.—A meeting of the radiological societies was held in London during the week ended May 21 last, to form an expert committee to investigate and report on the use of x-rays from all points of view. The recent death of Dr. Bruce Ironsides, radiologist of Charing Cross Hospital, from frequent exposure

to high-power x-rays has directed attention to the dangers attending the administration of the rays, and the question of the improvement of existing measures for the protection of the patient and operator will be especially considered. The meeting was called by the Röntgen Society and the objects of the investigation will be to report on: (1) The changes induced in tissues by x-rays and particularly on the blood changes. (2) The properties of the x-rays and the best means of controlling their action. (3) The equipment of x-ray and electrical departments with a special view to the protective measures employed. (4) Recommendations for the guidance of the assistants in these departments, particularly in relation to the hours of work and the need for fresh air and change.

Medical Students in Great Britain.—At the opening of the summer session of the General Medical Council Sir Donald MacAlister, the president, said with regard to the registration of medical students, that in 1919 registration rose to 3420, and in 1920 fell to the more manageable number of 2531. However, this number is still higher than any year prior to 1919. In his opinion it would be in the interests of sound professional education were the number still further reduced. They impose a severer strain, educational and financial, on the schools and hospitals than the necessary recruitment of the profession demands, and in present circumstances the teaching institutions are less able to meet the strain. To raise the educational standard for admission, and to increase the fees for professional tuition, would thus seem from all points of view to be justifiable.

Obituary.—Deputy Surgeon General, Retired, Sir Robert William Jackson, C.B., who died in Dublin on May 12 last in his ninety-fourth year, was probably the oldest medical man in Ireland. He entered the British Army Medical Department in 1854, served in the Crimean war and was present at the fall of Sebastopol. He served throughout the Indian Mutiny, in the Ashanti war and in South Africa. He was present at the battle of Tel-el-Kebir in Egypt.

LETTER FROM GENEVA.

(From Our Own Correspondent.)

GENEVA, June 1, 1921.

Indicanemia.—Dr. Lisbôa has recently carried out some clinical work at the Medical Clinic of the University of Geneva to ascertain the prognostic value of indicanemia. He searched for indican in the blood of 71 patients, 59 of whom presented renal insufficiency and these cases are the ones that need be considered. The 12 remaining cases were for the most part cardiac in nature, but it may be said incidentally that the test for indicanemia was negative in all twelve. The first 8 of the 59 nephritic cases gave positive results for indicanemia as follows:

	Indicanemia	Urea in Blood
Case 1	++	4.64 per cent
Case 2	++	2.87 per cent
Case 3	++	2.50 per cent
Case 4	+	2.08 per cent
Case 5	++	1.80 per cent
Case 6	++	1.70 per cent
Case 7	++	1.30 per cent
Case 8	++	1.25 per cent
	++	2.50 per cent

It is to be remarked that cases 7 and 8 had only 1.30 and 1.25 urea in the blood respectively, therefore a percentage lower than Tchertkoff (Indicémie symptôme d'insuffisance rénale. *Revue Médicale de la Suisse Romande*, Aug., 1917), considers necessary in order that his reaction shall be positive.

On the other hand, the patients comprised in the following table gave a negative result to the test for indicanemia, although the percentage of urea reached or exceeded 1.50.

	Indicanemia	Urea in Blood
Case 5	—	1.97 per cent
Case 9	—	1.50 per cent
Case 10	—	1.50 per cent
Case 11	—	5.28 per cent
Case 12	—	1.70 per cent
Case 13	—	1.75 per cent

As will be seen, Case 8 figures in both tables; the percentage of 1.97 urea was obtained shortly after the patient was admitted to hospital. At the end of three weeks, when her general condition was considerably worse, another blood examination showed a lesser amount of urea, viz., 1.25—which can be explained by the diet—but at the same time the indicanemia was positive.

In Case 13—a hyperacute nephritis causing death in twenty-four hours—indicanemia was negative, although the urea was 1.75. Such a rapid evolution may perhaps have prevented indican from accumulating in sufficient quantity in the blood to be detected and in favor of this hypothesis, Lisboa refers to Case 8, where three weeks was required before the indican reaction appeared.

Indicanemia was absent in Cases 9, 10, 11, and 12. In the first two the limit of the required percentage of urea may, on a pinch, be regarded as having been reached, but in Case 11 the patient had ingested large doses of mercury bichloride and was treated by intravenous injections of glucose serum. The nephritis underwent a rapid evolution, therefore, all these factors taken together are sufficient to explain the 5.28 urea without indican being detected. Finally, as to Case 12, the nephritis underwent a favorable evolution and the patient soon left the hospital about well. Consequently Lisboa regards this case as an argument in favor of the prognostic value of Tchertkoff's reaction. He also concludes that the prognostic value of this reaction is unquestionable in nephritis, and in not a single case in which indicanemia was positive did the patient live. However, Lisboa points out that it may be absent in fatal cases in which the urea is increased, but in his experience this only occurs in nephritides with a very rapid evolution with an evidently fatal outcome, so that the indican reaction would have no clinical utility in the circumstances. As the reaction can be made by any physician on account of its simplicity it is to be highly recommended.

To those unfamiliar with Tchertkoff's test it may be briefly described as follows: During fast 8 to 10 c.c. blood-serum is obtained by venous puncture to which an equal quantity of a 20 per cent. solution of trichloroacetic acid is added; after filtering, an equal quantity of concentrated hydrochloric acid containing six grams of iron perchloride per liter, is added to 10

c.c. of the filtrate. Shake and then add 3 c.c. of chloroform, and after again shaking several times examine in fifteen minutes. The chloroform becomes pale to dark blue, according to the amount of indican contained in the serum. If the serum contains traces of iodine the chloroform assumes a pink or pinkish violet hue, according to the amount of iodine present.

Neosalvarsan and Mercury in Tabes.—At the Dermatological and Syphilographic Clinic of the University, Dr. Danon has studied the results of the treatment of locomotor ataxia with neosalvarsan and mercury, his material consisting of nineteen cases. The syphilitic virus may attack not only the posterior columns but the cranial nerves and cerebral substance as well, so that the symptoms and progress of the process vary greatly from one case to another and consequently, in these circumstances it is difficult to define what may be considered a cure. If it be recalled that the onset of tabes is usually overlooked and the degenerative lesions have, therefore, time to develop into incurable lesions, it is clear that the definition of "cure" is difficult to state. For Danon a cure consists in an arrest in the evolution of the process dating from the time that an effective treatment has been given. Tabes is rare in patients who have been energetically treated in the early years of their syphilis, and, out of his nineteen cases Danon found that in ten the syphilis was unsuspected and, therefore, had never been treated. Excess in tobacco, alcohol or coitus, and especially fatigue of all kinds, is to be avoided, and to show that fatigue is not a negligible factor in the cure of tabes, Danon refers to one of his patients, who, after a salvarsan treatment, became pregnant, which obliged her to remain quiet. Gestation was normal and the patient delivered of a child free of any trace of hereditary syphilis, while the tabetic mother was very greatly improved as well.

Danon divides his cases according to the results of treatment into three groups—namely, on pain, on incoordination, and on other clinical symptoms. He finds that neosalvarsan unquestionably controls the lightning pains in the limbs and trunk, as well as gastric crises. Of the nineteen cases, twelve patients presented lightning pains, six were greatly improved, five fairly so, and in one there was a relapse. Gastric crises were present in four and neosalvarsan improved them in all four patients. The results obtained in incoordination are a matter for discussion, because re-education was practised. In two patients the incoordination was marked, in five others it was slight. In one of the severe cases neosalvarsan produced a slight improvement, in the second its effect was *nil*. In the mild cases of incoordination there was marked improvement in four. The other nosological phenomena of tabes are also favorably influenced by neosalvarsan. In three cases with ocular disturbances two were improved or at least the evolution was arrested. Headache was always relieved, while an improvement in the general condition was likewise noted, a well-marked eutrophic state and an increase in weight. One patient presented an epileptiform paroxysm

which did not recur after treatment was begun. Abolition of the reflexes and unequal pupils are two symptoms that are uninfluenced by arsenical treatment of locomotor ataxia, but Danon believes that this process can be cured by the therapeutic measures now at our disposal, and this is all the more probable the earlier in the evolution of tabes it is begun and continued until both blood and cerebrospinal fluid are definitively negative. The treatment must not only be very active, but continued after the blood and cerebrospinal fluid have been negative for some time. Lightning pains, vertigo, headache and gastric crises are the symptoms most usually and the most completely controlled.

Progress of Medical Science.

Boston Medical and Surgical Journal.

June 9, 1921, clxxxiv, 23.

1. The Prevention of Heart Disease—A New Practical Problem. Haven Emerson.
2. The Essential Factors of Cancer Causation. James W. Shannon.

1. The Prevention of Heart Disease.—A New Practical Problem.—Haven Emerson states that one may say with reasonable accuracy that cardiac diseases are responsible for one in every six or seven deaths. More than 1 per cent. of the entire population is suffering from some form of organic heart disease. There are from five to nine cases of heart disease for every cardiac death per annum. It will be accepted, therefore, that the detection of cases of cardiac diseases in their incipency is important to the community for the prevention and postponement of disability and death. As in the wise plan for the control of tuberculosis, periodical medical examinations, especially trained consultants to counsel with the general practitioner, and medical supervision of school children and industrial workers have been found effective, so similar benefit may be expected from the same method of attack upon heart disease. There is lacking any clinical or pathological information upon which to base even a presumptive curve of incidence of cardiac diseases by age groups. The ages at which communicable diseases chiefly occur, which are believed to be responsible for the majority of cases of valvular and muscular diseases of the heart, certainly fall in the age groups under 35, and a majority before the age of 10, and perhaps the largest number for any one age group before the age of 5. In support of this statement, the writer reports upon the experience of some of the special cardiac clinics of the Associated Cardiac Clinics in the City of New York. A total of 6808 patients are reported upon, of whom 4392 were active cases on May 1, 1921. Among the adults of this group, the histories of 927 appear to have been so carefully analyzed as to permit of a sound opinion as to the probable causative infection, as follows: In 331 cases, acute rheumatic fever; 207, acute tonsillitis; 122, syphilis; 78, scarlet fever; 47, diphtheria; 14, pertussis; 54, measles; 163, carious teeth; 7, chorea. Among 720 children patients at these cardiac clinics where case histories were particularly well reported and studied, infections as possible or probable chief etiological factors were given as follows: In 279 cases, acute rheumatic fever (growing pains, etc.); 282, acute tonsillitis or sore throat; 53, scarlet fever; 63, diphtheria; 130, pertussis (at one clinic only); 232, measles; 207, carious teeth (none at one clinic); 49, chorea (none at two clinics). The writer dwells upon the importance of cardiac clinics and classes and upon convalescent care. The most effective and constructive service for prevention and relief of heart disease is that close cooperation of school and clinic found where the examination of the children picked out by the school medical inspector is taken up by a clinic class operated in the school district, the chief of the cardiac class becoming the specialist adviser for the school and home career of the cardiac child, just as the tuberculosis

specialist has guided the anemic and pretuberculous child in the open air classes of the public schools. The prevention of heart disease is a practical public health problem because it is the cause of the greatest number of deaths and disabilities in the United States; because cardiac diseases fall within the class of preventable diseases, since their exciting causes, or infections, are severally communicable or preventable diseases, or both; because the individual has not the knowledge to, ing, treatment, employment or hazards of life alone, or escape by his unaided, individual effort, the origin and development of these diseases. The first step in the execution of the program of prevention is to make real to the general practitioner the possibility of prevention, the prevention of infection, the prevention of cardiac damage, the prevention of the extension of lesion or disability, and the postponement of death from heart diseases. All this means the introduction of a consciousness, a definite knowledge, and interest in the prevention of heart disease through medical education. Cooperation of the public and the profession is necessary.

1. Some Medical Problems: Presidential Address.—Hubert Work. (See p. 1032.)

2. Exercise Tolerance of Children with Heart Disease.—May G. Wilson conducted the series of investigations reported in this paper (1) to formulate a working table of standardized test exercises from a further observation of clinical symptoms and circulatory reactions following test exercise in normal children; (2) to compare the circulatory reactions after test exercises in the cardiac group with those obtained in the normal group, and (3) to determine the exercise tolerance of children with heart disease to standardized test exercises. The investigations were conducted upon a group of average normal children from 6 to 15 years of age, thirty-three girls and twelve boys, supplementing the previous study on twenty normal children, making a total of sixty-five children, thirty-seven girls and twenty-six boys; and a group of 116 children with heart disease, from 6 to 15 years of age, eighty-four girls and thirty-two boys. The conclusions drawn from these observations follow: 1. The circulatory reactions after test exercise in forty-five normal children, and in 116 children with heart disease, confirmed the results obtained in the twenty normal children of the previous study, in all essential points. 2. A working table was formulated of standardized test exercises followed by normal systolic blood-pressure curves without symptoms of dyspnea and fatigue. It was standardized from an analysis of the reactions of an average group of sixty-five normal children according to age, weight and height. 3. The degree of distress and type of systolic blood-pressure curve following standardized test exercises was used as a gauge in estimating the exercise tolerance of children with heart disease. 4. Of the seventy-one children having definite organic heart disease, without symptoms of insufficiency, 69 per cent. had a normal tolerance for standardized test exercises, 29 per cent. had a fair tolerance, and 2 per cent. had a poor tolerance. 5. In children with chronic organic heart disease, exercise tolerance tests gave important and useful information which may be utilized as a scientific basis for intelligent regulation of the child's

activities. The observations resulting from this investigation would seem to indicate that the fear of exercise is unwarranted, and that a wider latitude may be permitted with safety.

6. Relation of Increased Blood Viscosity to Transient Attacks of Hemiplegia.—William H. Holmes holds that in patients of advanced years, or those known to have vascular disease, and in those who have had cerebral vascular crises, dehydration of the tissues should be avoided. The introduction of anticoagulant salts and of fluid may be indicated in certain cases of transient hemiplegia or aphasia in order to prevent actual thrombosis in vessels when slowing of the circulation is the cause of the symptoms.

10.—American Children in the Tropics.—Nathaniel Bercovitz states, from observation and experience extending over six years' residence in the tropics, that healthy American children can be brought up in the tropics, and that no American need hesitate to go to tropical climates if the following conditions are met: 1. The housing facilities must be ample to secure plenty of space, good ventilation, and proper screening protection. From purely business considerations, no business firm should ask an employee to move to a place where housing conditions are not of the best. 2. The wife and mother must be prepared to enter on a period of ceaseless vigilance and cooperation with the physician in (a) problems of nursing and feeding of infants; (b) sterilization of drinking water and food; (c) fighting against flies and mosquitos, and (d) care of the skin, and the protection of children from the heat of the sun and from chills. 3. No family should live in a place where good medical care is not available at the shortest notice. Many tropical diseases are quick and deadly in their action, especially in children. 4. Frequent (yearly) changes from the heat into a cooler climate should be possible for mother and children. Of these conditions, the most important is the responsibility resting upon the wife and mother, from the moment of the birth of the child, through the nursing period, especially if there are difficulties of feeding, until the child leaves the tropics for study at home.

1. The Goulstonian Lectures on Glycæmia and Glycosuria.—George Graham, in the first two of this series of lectures, discussed the fate of the sugar in the blood, and the types of diabetes mellitus which are already recognized. In the present and concluding lecture he discusses briefly the hypotheses for the cause of diabetes, and the principles and details of the modern treatment. The account of the etiology, he holds, shows how little is really known in spite of the great advance which has been made. Similarly, the treatment has been improved out of all knowledge since 1915, but the disease remains a dread disease. It is true that life is prolonged for several years in the severe cases, and that during most of that time the patient feels comparatively well, yet the treatment is in no sense of the word a real cure. The most that one may hope to do at present is to arrest the disease, and in order to do that the dietetic restrictions must be severe and carried out with the cooperation of the patient.

4. The Action of Digitalis and Atropine on the Peripheral Blood Pressure.—I. Harris, in this study, from the relation between blood pressure and pulse frequency makes certain deductions with regard to the influence of these drugs on the general circulation. The leading idea of the paper is to make the output of the single contraction a sort of criterion by which the effects of these drugs are to be gauged. It is assumed that a large systolic output will give rise to a correspondingly

large pulse-pressure reading and vice versa. The observation was conducted at the heart clinic of the Northern Hospital, Liverpool. Digitalis was prescribed, and blood pressure and pulse tracings were taken before the administration of the drug and once weekly while the patient was under its influence. Under the influence of digitalis, it was found, the diastolic pressure becomes lower and incidentally the systolic, while pulse pressure rises. The decline of the diastolic pressure is not due to a diminished output of the heart—the contrary is the case. The low diastolic pressure is never due to dilatation of the arteries. The conclusion is that the blood stream leaves the arterial circulation at a greater rate than under normal conditions. The corollary to this conclusion is that under digitalis the heart contains at the beginning of the systole a greater amount of blood than before. The quickening of the pulse observed in the latter stages of digitalis is due to the fact that in a shorter time than normal the intra-cardiac pressure is sufficiently high to excite contraction.

1. A Clinical Lecture on Acute Infective Arthritis.—F. J. Steward reminds one that the ways in which a joint may become infected may be arranged conveniently in four groups: 1. From the exterior, due to accidental and gunshot wounds. 2. By spread from neighboring parts, especially in cases of acute infection of one of the bones forming the joint. 3. By metastasis, from an infective process in some other part of the body. 4. In general blood infection. The synovial membrane, in a case presented, as in others, played an important part, and much depended upon whether its resistance was equal to the occasion. It was necessary that such treatment should be adopted as would aim at supporting that resistance in every way possible. Particular emphasis was laid by the writer upon the local characteristic of the synovial membrane of a joint which enables it to deal with infection probably even more efficiently than the peritoneum. War experience emphasized this, for results clearly show that the best way to treat a joint infected by a bullet or piece of shell or clothing was to remove the foreign body, cleanse the joint so far as possible, close the wound, and let the synovial membrane do the rest. The synovial membrane may be assisted in the exercise of its function by treatment: 1. By letting out the pus. By so doing the blood supply to the synovial membrane, which must be greatly interfered with by the direct pressure of the pus, will be restored, in addition to getting rid of the local and general poison. 2. By keeping the limb at rest by the application of a suitable splint with extension. The extension is very necessary in order to overcome the pain, and so render the patient comfortable and able to rest. 3. By the injection of antiseptics into the joint. The necessity for this is by no means certain, and, although it has been held to be of great service by some surgeons, its value must be to a large extent, problematical.

6. Comparative Systolic Blood-Pressure Readings in the Arm and Leg in Aortic Incompetence.—O. K. Williamson bases this paper on his observations of 24 cases of undoubted and, indeed, well-marked aortic incompetence. His conclusions follow: 1. Although higher systolic readings in the leg than in the arm appear to occur in the majority of cases of aortic incompetence, there is a large minority in which they do not obtain. 2. There is no evidence that such cases, when they do exist, are the result of the actual aortic incompetence rather than of the commonly associated

condition of hypertonic contraction or hypertrophy of the muscular coat, with or without accompanying sclerotic changes, conditions which also occur independently of aortic incompetence. 3. In support of the arterial explanation of such differences is the fact that the large majority of cases of the series in which the arteries were thickened showed the difference, being a much larger proportion than obtained in the total number of cases of the series (all of which had aortic incompetence); and further, that in the adult cases of aortic incompetence, nearly all of which had thick arteries, the phenomenon was more than twice as common as in the children in none of whom were the arteries thickened. 4. If due to the aortic incompetence it would seem reasonable to suppose that the difference of reading should show some relationship to the degree of incompetence, which for practical purposes may be considered as measured by the pulse pressure. No parallelism, however, exists between these arm-leg differences and the corresponding degrees of pulse pressure. 5. In the few cases in which this was tried, in the majority the difference of pressure was abolished by repeated recompression, a fact decidedly in favor of the arterial explanation. (In cases of a higher leg reading than that in the arm in arterial disease it has been frequently found that the difference is abolished by such recompression.)

4. The Surgical Treatment of Empyema by a Closed Method.—Arvine E. Mozingo for eighteen months had charge of the empyema wards at Walter Reed General Hospital, Washington, D. C., and at the Base Hospital, Camp Pike, Arkansas, during which time he developed what he calls a closed method of treating empyema. This communication is based on a series of 138 cases, 45 acute and 93 chronic, treated by him by this method, with a mortality of less than 2 per cent. The technique of the method is described in detail. From his experience in the series and from a comparison of the closed method with others, the writer draws the following conclusions: 1. Early operation by the closed treatment method has the following advantages: (a) It can be done, regardless of the stage of pneumonia or serious condition of the patient, without the least shock or collapse of the lung. (b) It provides complete evacuation of the empyema cavity, relieves cardiac and respiratory embarrassment and prevents the absorption of toxins and the usual resultant complications. (c) It lessens the usual thickening of the pleura and prevents the lung, compressed by the exudate, from becoming fixed in compression. 2. The closed method has the following general advantages: (a) Productive of great economy of time, labor and dressing material. (b) Causes minimum pain and discomfort to the patient. (c) The dressing is small, lasts several days, without skin irritation, and does not constrict the chest. (d) Uncomplicated cases of empyema are not kept in bed. (e) Cases are less likely to have recurrence, become chronic, or need a secondary operation. (f) The constant negative pressure gives maximum expansion of the lung. (g) The scar is very small and there is no chest deformity. (h) Practical in the home and in country practice. (i) The postoperative treatment in greater part may be done by a nurse or a properly instructed

member of the family. (k) Bacteriological and roentgenographic laboratories, while always to be preferred, are not absolutely essential. (l) The mortality is lower than by any other method. (m) Can effect cure in acute bilateral empyema, both sides being operated at the same time, with acute bilateral pneumonia present, which treatment is impossible by the open method. 3. Dakin's solution, because of its great solvent and bactericidal action, is the most nearly ideal solution to use in the preliminary treatment of the empyemic cavity to dissolve the fibrinous exudate and partially sterilize the cavity. 4. Liquor formaldehyde in glycerin, 2 per cent. dilution, is the best solution to use in the empyemic cavity after the preliminary treatment with Dakin's solution, to complete sterilization, shorten the course of treatment, and prevent a recurrence. 5. Smears and cultures after the formaldehyde solution treatment is begun will each show a rapid decrease in the number of bacteria, which are sometimes found two or three days in the smear after the culture will be sterile. 6. Bronchial fistulae are more common than is generally suspected. With this complication salt solution should be used in amounts as large as possible but not to cause the patient to cough. 7. A hypochloride solution of increased strength over Dakin's solution in both alkalinity and available chlorine can be used in the empyemic cavity with safety. 8. The available chlorine in Dakin's solution after injection into the empyemic cavity rapidly decreases. The strength after one minute averages 0.38 per cent., and after five minutes 0.07 per cent. 9. Dakin's solution can be made with sufficient accuracy from various commercial products by those who do not have the usual facilities for making and testing this solution. 10. The progress of acute cases when less frequent treatments were given indicates that cures can be effected in a little longer time by giving only one to three treatments daily. 11. Cases becoming chronic following open operation generally can be cured in a comparatively short time by instituting the closed method treatment, so making unnecessary a major secondary operation of the Schede, Eastlander or Delorme type.

6. The Transfusion of Blood with Report of 186 Transfusions.—I. S. Ravdin and Elizabeth Gleen trace the history of transfusion, give the indications, discuss the amount of blood to be transfused and the selections of donors, and describe the method employed in the hospital of the University of Pennsylvania. The series of cases include one arteriovenous suture, 47 transfusions by the Kimpton-Brown method, and 138 by the citrate method. The following deductions are drawn from this experience: 1. With the element of risk practically eliminated blood transfusion has become one of the most effective procedures in modern therapeutics. 2. Transfusion is a specific in acute hemorrhage where the "limit of bleeding" has not been reached, in melena and in the hemorrhage of hemophilia. 3. It is of definite value in primary pernicious anemia in hastening and prolonging remissions. It is indicated in cases of severe secondary anemia. After transfusion operations on debilitated or anemic individuals may often be safely undertaken that otherwise would involve serious risk. 4. Transfusion in shock is not as efficacious as in cases of shock associated with hemorrhage. 5. They have not been able to prove the value of transfusion in acute infections, but in chronic infections have had results justifying its use. 6. Transfusion is of unproved value in acute leukemia. In aplastic anemia it is at the most a temporizing procedure. 7. The difference, as far as reactions are concerned, between the citrate method and the Kimpton-Brown method have been found to be practically nil, and such being the case the simplicity of the former warrants its preference.

Allergic Nature of Scarlet Fever.—Schiff claims that the original exciter of scarlatina conjoined with the streptococcus causes the outbreak of disease proper, while the severe postscarlatinal complications are due to an allergic sensitization by the same symbiosis. The blood picture recalls that of serum disease but appears late or during the postscarlatinal period. Relapse of the disease has an analogous mechanism.—*Jahrbuch f. Kinderheilkunde*.

(Special Report to the MEDICAL RECORD.)

SECTION ON DISEASES OF CHILDREN.

(Continued from page 1086.)

Heart Disease in Children of School Age.—Dr. ROBERT H. HALSEY of New York presented this contribution. He stated that just before the war an investigation was started to make a study of heart disease as it occurred in school children in New York City. At the same time the Association for the Prevention and Relief of Heart Disease was organized, and classes for cardiac children started. A large number of organizations had had a part in the work in addition to his department at the Post-Graduate Hospital. In order to learn something about the incidence of heart disease among school children they selected seventeen public schools from which the children were sent to them. Forty-four thousand children registered with them and of this number there were 948 that they had reason to believe were heart cases; 443 were found to come within the group which had been used to classify the cases attending the cardiac clinic. This classification was as follows: 1. Those having organic heart disease who were able to carry on their habitual physical activities. 2. Those having organic heart disease in whom there was a slight diminution of activity or even a great diminution of activity, but who were still able to carry on some activity. 3. Those having organic heart disease and not able to carry on their activities. 4. Cases, possibly heart disease, which were not able to carry on physical activity. These were called the accidental group, some of whom might develop actual heart disease. 5. Potential heart cases. Of the 948 cases, 228 fell in the first three groups. In group 4 there were 163 cases. Only one-half of one per cent. of the 44,000 cases had actual organic heart disease. Of these having organic trouble, 77 per cent. mitral lesions and 9 per cent. had aortic disease. The acquired lesions amounted to from 87 to 89 per cent., leaving 14 per cent. which might be considered to be congenital. A Group 1 child was thought not to require any special attention. In a study of 125 cardiac children the histories showed tonsillitis in 65 per cent.; rheumatism in 45 per cent.; measles in 36 per cent.; pneumonia in 18 per cent.; diphtheria in 21 per cent.; chorea in 18 per cent.; pertussis in 17 per cent.; scarlet fever in 12 per cent. Measles in normal children had an incidence of 58 per cent. and whooping cough of 33 per cent. Tonsillitis, chorea, and rheumatism were much more common in cardiac than in normal children, whereas measles and whooping cough were much more frequent in normal than in cardiac children. The reason for the lower incidence of measles and whooping cough in the cardiac child was believed to be due to the fact that he was not allowed to come in contact with other children to the same extent as did the normal child. The statement was often made that the gathering together of a group of children with heart disease had a depressing effect upon the children which was distinctly bad. That was not the case in these children; on the contrary their outlook on life was better as they came to feel that they were able to do something. The attitude of teachers and parents was changed when they felt that there was something these children could do. The philosophy of handling these children lay in teaching them to do the things that were within their capacity. The practical classification which had been presented was a valuable aid in differentiating and managing cardiac children. By careful attention to improving the nutrition of the children and by regulated graduated physical exercise which included improving the carriage and posture of these children, they had been greatly improved. This improvement was evidenced by the improvement in their general condition, in their alertness, precision and ability to carry on with less mus-

cular effort. The better school attendance of these same children after supervision bore witness to the value of the methods used.

Dr. WILLIAM ST. LAWRENCE of New York said he thought those interested in the cardiac problem had listened to Dr. Halsey's paper with a great deal of interest because he had started upon an experience which would aid in solving the question of the attendance of the cardiac child at school. The places where the work Dr. Halsey had reported overlapped that in which he had been interested showed that their results were in harmony at these points. In Dr. Halsey's series of cases, the second group included a much larger number of children than one found in the rank and file of cardiac cases. In his experience 75 per cent. of cardiac children had exercise tolerance and 25 per cent. had a relative amount of exercise tolerance. There were only a few who had such a diminished exercise tolerance as to be a problem. In only three per cent. of the children in their clinic had the exercise tolerance been sufficiently low to be a serious factor. As to the proper care of the cardiac child, attention to the tonsils, a proper amount of sleep, a suitable diet, etc., played an important part. After these matters were regulated a great deal of attention need not be directed to the question of exercise. The child as a rule tended to seek his own exercise level. One did not as a rule need to prescribe physical exercise. Adults did not tend to seek exercise but children were naturally active. As to the result of therapeutic exercise in adults he could not speak but in children he did not see dramatic results.

Dr. HAVEN EMERSON of New York expressed the belief that in Dr. Halsey's paper and those of Dr. Lawrence it must be apparent that there had been thrown open a large field for preventive medicine. The whole thing was in the hands of the private physician. In dealing with this disability there was an opportunity for the private practitioner to come into his own. The outcome was going to depend upon the keenness of the profession in handling it. We had seen the death rate of tuberculosis drop from 250 per 100,000 to 124 as a result of efforts to control that disease. The mortality from cardiac disease still stood at 200 per 100,000 population. Approximately one per cent. of the population had tuberculosis and there was practically the same incidence of active cardiac disease. In New York City they had 30 clinics for tuberculous patients and 8 per cent. of sufferers from tuberculosis attended these clinics. We now had an equal number of cardiac clinics and that number was probably sufficient for the community. In the regulation and control and prevention of tuberculosis and communicable diseases they did not get control of the situation until more cases were reported than actually occurred of the diseases under discussion. It was equally true that we would not reach the true worth of cardiac clinics until more cases of cardiac disease sought treatment than actually had heart disease. This promised to be a step toward the annual overhauling of everyone. These cardiac clinics were developing unconsciously the ability to diagnose heart disease before the patient knew he had it. If the situation was properly handled the cardiac clinics would have not only the opportunity of finding early cases of tuberculosis, but they would get the cardiac in the incipient stage. The cardiac patient today did not come to a clinic until four to eight years after he had first observed symptoms. It used to be that the tuberculous patient did not come to a clinic until his disease was far advanced. He thought the problem would have to be segregated and that they would have to have not only special preventive and diagnostic clinics but a service to give temporary relief in cases of periodic decompensation.

Dr. GEORGE DOW SCOTT of New York expressed the view that it was impossible to put down a general statement for the general physician as to the management of cardiac cases. It was not difficult to say which patients should be put to bed and which should not be put to bed, but there was a large group of cases, the so-called functional murmurs, that should be put to bed only as long as was necessary and should be allowed to be up as soon as possible; others should not be allowed to know of their condition. In many cases that he had seen he had not told the mothers or the

patients that heart disease was present. He had told them to go on with their regular exercise and their natural normal play. He felt that play was far better than regulated exercise. With normal play and proper nutrition these children with functional murmurs got on well. About 90 per cent. of these children had mitral regurgitation and he only put them to bed long enough to get them back on their feet. In his estimation there were many potential heart cases not due to tonsillitis or to rheumatism or chorea but to malnutrition, because an enormous amount of protein formed the basis of their diet. Many of these cases came with meteorism, constipation or not constipation and with tonsillitis, or without tonsillitis, and in many of them the diagnosis of incipient heart disease had been made. Those cases should not be relegated to a place where there were segregated cases. To segregate these cases and center their attention on the cardiac condition was wrong. The heart was a muscle and the more it was developed under proper regulation the better and quicker would the individual be able to carry on. He knew of cases of this kind that had been allowed to carry on normal activities which were better off today than they were twenty years ago.

Dr. C. H. WAHRER of Fort Madison, Iowa, said that sometimes these heart cases were very serious and one felt that they were not very hopeful cases, but they should not be given up. In reality they were very hopeful cases. In decompensation in children one should support the heart and unload the portal system; the latter was very important. He cited a case of the worst kind of decompensation in which he had followed the plan of treatment he had mentioned. In three weeks the child was taking graduated exercise and in three months she was able to climb an elevation of seven hundred feet and to resume her studies. Today she had complete compensation. The main point in handling these cases was never to give up.

Dr. HERMAN SCHWARZ of New York said it was due Dr. Halsey and his associates to explain just what they, with the aid of the City of New York, were trying to do. There was a surprising difference between the children one saw in private practice and those that came to the dispensaries in New York City. For many years it was a terrible thing to see one cardiac after another come to the dispensaries and all they did was to send them home. They were glad everyone was becoming interested in the care of cardiac children. There was no question as to the value of the work. The question was how to do it. They had first tried the convalescent home, but there were too few of these institutions, and now they were trying the cardiac classes in the schools. Those cardiac classes through Dr. Halsey's instigation had tried to supervise the child during most of the day. They used to be told when the children went home the mothers did not have time to look after them so these cardiac classes were formed which took care of the children from 8.00 A.M. to 5 P.M. which was a great step forward in the care of cardiac children among the poor. Branch cardiac hospitals were needed; such hospitals should be connected with general hospitals, where a child with marked decompensation might be put to bed under good medical care and remain months or even years if necessary. He could, when ready, be graduated into the cardiac schools and then graduated into adult life and do good work. Dr. Schwarz said he had a dream of such plan. The discovery of the etiological factor in rheumatism would obviate a great deal of the difficulty surrounding the solution of the problem of cardiac disease in children.

Dr. HALSEY, in closing the discussion, emphasized the advantages of the classification of heart disease which he had presented. With reference to the question which Dr. Scott had raised he expressed the opinion that it was all wrong to say that the cardiac should not know of his condition. That was one of the very important advances that had been made in the treatment of heart disease. If one was going to get the cooperation of the people among whom the cardiac child lived he must tell them what they had and what could be done for the condition. They must be told that a great deal could be done for these children and how far they could go as regards exercise and when

they must stop. That was what was being done by the clinics. What could be the objection to the segregation of these children—of sending them to a man specially interested in cardiac disease who had a special knowledge which was entirely technical and diagnostic? They used the fluoroscope and the electrocardiograph for what information those instruments could give though they did not make the diagnosis of heart disease. As to the question of food for the cardiac child, the little patient needed food so far as he could take care of it. One should not get the idea that one protein was as good as another. All meat should not be excluded from the diet. Some had spoken of the Class 3 children or those with heart failure. He had not gone into that group because he was speaking more particularly of the children in the schools. One more question was brought up and that was what they were trying to do in New York. They were trying to find the solution of the problem and this was only preliminary work. They had tried this plan with the small group of 44,000 out of the 800,000 children in the public schools. As in any work of this kind the assistance of well educated, tactful social workers was essential. A social worker could take care of about one hundred children and no more. Beyond that she could not find time to look after the individual child. The child's temperature and pulse were taken every day. Not to know what the temperature was but know whether the child was running a temperature as a regular thing. The social worker did many things beside taking the temperatures. She gained the confidence of the child and that of the mother so that instructions would be carried out, and to be in a position to get her cooperation if a tonsillectomy were necessary or for whatever they believed should be done. This propaganda was in its infancy and it was essential that they should have a proper boost.

The Treatment of Furunculosis in Infants.—Dr. CLIFFORD G. GRULEE and MISS CASSIE BELLE ROSE of Chicago presented this communication in which the relative merits of the treatment of furunculosis by means of antiseptic ointments and liquid antiseptics were discussed, and their inadequacy pointed out. They had tried a combination of the treatment by antiseptic solutions and the x-ray. Dr. Pancoast recommended the application of doses of x-ray two to four sittings over a period of two weeks. They had not attempted the treatment of furunculosis in babies. The difficulties of treating infants with the x-ray and their susceptibility to the x-ray were well known. In one instance some of the furuncles were treated while others were left untreated. The individual furuncles treated subsided but the x-ray did not prevent other furuncles from appearing. In a general way their impression of the x-ray treatment of furunculosis was favorable, though the series was too small to warrant a statement as to the ultimate results as compared with other methods of treatment. It was better to use the soft ray and no filter. Certain reactions had occurred so regularly following the use of the x-ray in this way that they suggested that others employ it in order that a just estimate of the value of this form of treatment might be reached. It had not done away with the necessity for surgical procedures, but it had reduced the necessity for opening furuncles where they were superficial. They felt that there was ground for the hope that the x-ray might add materially to their means of treating furunculosis.

Dr. MEYER SOLIS-COHEN of Philadelphia stated that the results of the vaccine treatment of furunculosis had been rather unsatisfactory, but they could see the explanation in some work done recently. The blood of animals immune to a disease killed the organisms that caused that disease while the blood of animals susceptible to the disease did not kill those organisms. For instance, if the fresh blood of a chicken killed the pneumococcus that chicken was immune to that type of pneumonia. Kolmer had found the same thing true of the meningococcus. Another investigator had found that the blood of rats immune to diphtheria killed the diphtheria bacilli while the blood of animals not immune did not kill the diphtheria organisms. Dr. Heist and the writer had applied this method to various infections and they had found that it was true of furunculosis. Dr. Solis-Cohen then described a method they

had used in preparing a convalescent serum for use in furunculosis, and also a method of making vaccines. They had found that furunculosis would respond to these methods of treatment.

Dr. GRULEE, in closing the discussion, said in reply to the question as to whether he had used the x-ray in pemphigus in the new born, that he had not had the temerity to try the x-ray in the new born because the skin of a new born infant was too tender to run that risk. As to the vaccines, it was quite a while since he had abandoned their use as he had never gotten any good results. Where the results appeared to be good he thought it was merely a happening. He had had no experience with the methods Dr. Cohen had described.

The Beneficial effects of Tonsillectomy Upon Cyclic Vomiting and Allied Affections.—Dr. ALBERT H. BYFIELD of Iowa City read this paper in which he gave a brief review of the important aspects of cyclic vomiting. Among the points that had impressed him was the fact that in the large percentage of cases cyclic vomiting began in the second year; another point was the high percentage of true migraine in the parents of children suffering from cyclic vomiting. In his series of 27 cases 16 were blondes and 4 were brunettes, while in seven no observation was made on this point. This raised the question whether the preponderance of blondes was more than a coincidence. Pyuria was present in many of the cases during and between the attacks. The most prominent symptoms were nausea, vomiting, abdominal pain and light-colored stools; some cases were atypical and were called simple bilious attacks. Cyclic vomiting seemed to have a neuropathic content. The child who suffered from cyclic vomiting was born of a strain that was impaired, as evidenced by the frequent history of migraine in the parents. The preponderance of blondes suggested the possibility of that the exudative constitution might play a part if one admitted as some claimed that blondes were more likely to have the exudative constitution than were brunettes. It was also pointed out that the arthritic diathesis might have a relation to cyclic vomiting and some had held that the exudative and the arthritic diseases were perhaps identical. The production of acetonuria by starvation did not always bring on an attack and it was a question whether acetonuria played a prominent etiological part. Attempts to control the disease had not always given the results desired. There was a suspicion that the Jersey cow was a common source of trouble. The calf of the Jersey cow frequently could not take its mother's milk, and only a human being would be so presumptuous as to give to a child a milk with such a high fat content. In a few cases removal of the appendix had brought about relief and cure. Dr. Sedgwick and Dr. Rude Taylor had called attention to the tonsils as a source of infection that might be responsible for recurrent attacks of vomiting. Of the 27 cases in this series, 20 in which dietetic measures had failed were operated upon for removal of their tonsils and adenoids. Of these 10 had had no further attacks; four had had three attacks and then none. Thus 14, or 47 per cent., were cured by tonsillectomy, according to the statements of the parents. Four were improved and of these two had sinus and nasal infection. Two of the 20 reported no improvement. Of the seven cases not operated upon only one was cured; the parents of four of the children were positive that the child was not improved. In one instance in which removal of the appendix had failed to give relief, removal of the tonsils and adenoids caused a prompt disappearance of the vomiting. Dr. Byfield called attention to a tendency to regard recurrent vomiting as an acidosis. Acidosis was a complication and not a cause of the condition, and acetonuria occurred in many other conditions. The main points in the medical treatment of these cases was the avoidance of the indulgence in excessive amounts of fat; undue nervous strain should also be avoided. Where medical treatment failed to give relief conservative surgery was justifiable. Incomplete removal of the tonsils might fail to give relief.

Dr. JOHN ZAHORSKY of St. Louis stated that this class of vomiting cases was often dependent upon some infection of the tonsils, and when that was the case the children were benefited or cured by operation. By

watching these cases and seeing them repeatedly one was often able to come to the conclusion that there was an infected focus. However, those cases due to infection of the tonsils, adenoids, and nasal sinuses should be differentiated from cases of neurotic cyclic vomiting. He had had two cases in which the attacks of cyclic vomiting came on after complete operations by the best operators but these were children of the neurotic type. In cases of cyclic vomiting one should always have corroborative evidence of local infection in the tonsils and adenoids before recommending operation.

Dr. E. P. GENGENBACK of Denver, Col., stated that it was easy to differentiate these cases. By examining the tonsils one would usually find that the vomiting was associated with tonsillitis in cases in which the tonsils were infected. There was no question that focal infection was harmful to the individual and if the infected tonsils were removed the child would be improved but one must have the courage of his convictions. One should not omit the examination of the tonsils when treating a case of cyclic vomiting, and if they were found infected he should insist upon their removal.

The Physiology of the Blood in Infancy and Childhood.—Dr. WILLIAM PALMER LUCAS of San Francisco presented this contribution in which he gave some of the results of a comprehensive morphological study of the blood cells and hemoglobin in the new born, and emphasized the point that the study of the blood as a tissue gave much information as to what was going on in the body. What was just as important, if not more so, was that such a study gave a fair idea of what was going on in other tissues and organs. Directly, it furnished a conception of the existing state in the blood-forming tissues, as the bone marrow. An analysis of the various factors of the blood supplied a means of studying directly the functioning power and the potential capacity under strain of different organs, as the kidneys, liver, lungs, and, to a certain extent, of the conditions existing in the tissue cells throughout the body at the time of the study.

Second Day, Thursday, June 9.

Diagnosis and Treatment of Infectious Diseases.—Dr. DENNETT L. RICHARDSON of Providence, R. I., presented this communication in which he said that very few physicians realized the extent of infectious diseases and the prominent part they played as a cause of sickness and death, and particularly the place they held in the mortality tables in the United States. In the registration area of the United States, in 1918, of 1,471,367 deaths, 490,275 were due to infectious disease. In other words, infectious diseases caused one-third of all deaths in the United States in that year. However, 1918 was the influenza year. The average number of deaths due to infectious diseases was about 244,681. The actual number was in reality much larger. Eighty or 90 per cent. of these deaths occurred in children under 12 years of age. It was important that all physicians, and particularly pediatricists, should be taught to diagnose infectious diseases and to know how these were transmitted from person to person. Few medical schools put the teaching of infectious diseases in the hands of those who were experienced in the treatment of such conditions, namely, physicians in charge of contagious hospitals. Students graduated with the idea that scarlet fever always presented a definite clinical syndrome, whereas there was a considerable percentage of cases that did not conform to it. The schools could easily teach the cause of each disease, by what routes it escaped from the body, how soon the patient became infected, for how long it continued to be infectious, and what diseases developed the carrier condition. The diagnosis, however, could only be taught in a contagious hospital. This was a training which no pediatrician could afford to omit, since these diseases were chiefly seen in childhood. The new hospital for contagious diseases would care for erysipelas, typhoid fever, meningitis, poliomyelitis, syphilis, gonorrhea and other infectious diseases as well as of scarlet fever, diphtheria, measles and smallpox. Infectious diseases did not belong in a hospital where other diseases were cared for. The acute infectious

disease hospital might be located on the grounds with the general hospital but it should be manned by physicians and nurses who knew how to treat and nurse infectious diseases. If we had had properly trained physicians to care for infectious diseases we would not have had to pass through such an experience as we had during the World War when so few physicians and nurses were trained to care for this class of diseases. All children's hospitals should be conducted along the lines of contagious disease hospitals. An aseptic nursing technique should be carried out in contagious disease hospitals, since it had been fairly well demonstrated that diseases were rarely air-borne. By the use of aseptic technique cross infections in the Providence Municipal Hospital had been reduced as low as one per cent. More than one-half cross infections were due to measles and chickenpox. Our knowledge of infectious diseases was very limited. Of this the average practitioner was not aware. Our text-books on contagious diseases were very faulty. We had not made the progress in the knowledge of these diseases that should have been made. Scarlet fever was as prevalent as ever and diphtheria was more common than it should be. The statement that 90 per cent. of all scarlet fever cases were cared for in hospitals was not true.

Dr. EDWIN H. PLACE of Boston said that so far as the hospital went he thought a great deal of misunderstanding occurred among laymen and even among physicians as to the methods of isolation of contagious disease which had always been used. The Boston Hospital, which was started in 1891 and occupied in 1895, had certain elements in its arrangement that indicated that people believed that disease was air borne. Many did not believe in the cubicle system as they did not see how contagion could be prevented when there was open air space above the cubicles. It was rather strange that while people had recognized the need for insulation and had provided adequate screening, they had made no provision for guarding against infection from linen or hands. The doctors had had to wash their hands in the contagious hospital in 1900 and subsequently with a bowl and pitcher. This was an illustration of how slow hospitals had been to carry out in practice well known facts with reference to the prevention of contact infection. He disagreed with the statement as to the difference in the spread of measles and chickenpox as compared with diphtheria and scarlet fever. He did not think the spread of measles and chickenpox was any different from that of scarlet fever and diphtheria. There was a difference in the susceptibility of the individual; that was the only difference. He knew of one instance where measles and scarlet fever were in the same ward service. They had the same ward service from the same nurses and the same diet kitchen. There was no instance of measles being carried into the scarlet fever ward but there were many instances of scarlet fever being carried into the measles ward. Measles required much more direct contact than scarlet fever, but scarlet fever might be carried on the clothing.

Dr. HENRY BERG of New York said he was connected with a large contagious disease hospital and unfortunately polyinfections occurred quite frequently, though he did not know that it occurred more frequently now than it formerly did. If any doctor could tell us how to prevent polyinfections he would do an inestimable service to humanity. There were many infections not transmitted. Typhoid fever and diphtheria were not transmitted, and the reason was because we knew the organism. We knew how it entered the body and how it was extruded. The trouble with measles and scarlet fever was that we did not know the organism. He feared that we should never be able to prevent polyinfections until we knew the causative organisms of these diseases, their life history, clinical characteristics, transmissibility, the way they acted, and the way they were extruded from the body. He knew of no greater misfortune than that a child should be admitted to the hospital for measles and then should have scarlet fever, and diphtheria. The man who could designate, not in general terms but specifically, how these polyinfections could be prevented would be one of the greatest benefactors of humanity.

Dr. C. H. WAHRER of Fort Madison, Iowa, related

an instance in which a doctor treated several children in a family for scarlet fever and then three weeks later confined the mother. She became infected and three laparotomies were necessary. She was living but had passed through death to life. A doctor who was treating a scarlet fever case should know enough to keep his hands off of other cases while he was doing it.

Dr. A. W. PLUMMER of Lisbon Falls, Me., said he would be glad if the author of the paper would vouchsafe some information with reference to the diagnosis of scarlet fever on a point he wished to raise. He had had two cases in which so far as he could see the only symptoms of scarlet fever were temperature, rapid pulse, vomiting and sore throat, and in one a strawberry tongue. In one of these cases he had had a consultation and the diagnosis of scarlet fever was confirmed. In neither case were there any signs of desquamation. The question he raised was whether his diagnosis was correct and whether others had seen similar cases.

Dr. RICHARDSON, in closing the discussion, said he did not want to give the idea that chickenpox was carried by the air. It was a long story but they would find out sooner or later that these were surely contact diseases. Relative to the last speaker's question about scarlet fever, it did not matter how many contagious diseases a man had seen he could not diagnose them all. There was a considerable percentage missed because we had no means of recognizing them. Probably not more than 30 per cent. of scarlet fever cases had strawberry tongue. Many times he had seen a sore throat in a child in a family in which there had been a case of definite scarlet fever and in such a case one was justified in making the diagnosis of scarlet fever on the grounds of exposure, whether the child had a rash and strawberry tongue or not. There were many more cases of diphtheria that did not show a membrane than of those that had a membrane. With known contact he had the suspicion that measles might occur without any rash whatever.

Certain Aspects of Postdiphtheritic Diaphragmatic Paralysis.—Dr. HAROLD R. MIXSELL and EMANUEL GIDDINGS presented this paper, in which they gave a résumé of the subject and discussed the anatomy and pathology of phrenic nerve involvement by the diphtheria toxin and toxon. The frequency of diphtheritic paralysis was higher than one would suppose, being 8 per cent. of all cases of paralysis and 0.2 per cent. of 4259 cases of diphtheria. The average date of onset of the paralysis was 39½ days after the onset of the disease. Death usually occurred within forty-eight hours. The symptoms were those of respiratory failure. There was no active treatment by means of drugs when the damage was done by the diphtheria toxin. Marriott had reported a case in which artificial respiration had resulted in tiding the child over the acute stage of respiratory failure. The child ultimately recovered. The writer reported eight cases and stated that the prognosis was 100 per cent. fatal. In view of this fact treatment by means of intratracheal insufflation, the pulmotor, and the Erlanger-Gessel apparatus was worthy of trial.

Dr. ROBERT J. WILSON of New York said he was glad to have a paper of this kind emanate from Willard Parker Hospital because it showed that the hospital was taking its place as a teaching institution. They were all familiar with the unreliability of statistics. These statistics were reliable but they came from an institution notable because it received the many cases in a hopeless condition. So in a way it might be taken that the proportion of cases of paralysis was far too low. A second point Dr. Wilson made was that if the doctors in New York City had been doing their duty since the discovery of antitoxin there would not have been a chance to report these cases. All this was preventable. It was the duty of the American Medical Association to see that the people themselves and the mothers were educated, as far as possibly could be done, to a sufficient degree to know when to call a doctor, and that the doctor be sufficiently intelligent to know when to give antitoxin, and to know that he should not wait for a Schick test or a culture.

Dr. HENRY BERG of New York thanked Dr. Mixsell for this extremely interesting series of cases. These

cases were important because they were fatal and furthermore because every bilateral phrenic nerve paralysis was fatal. It occasionally happened if one could make the diagnosis when the paralysis had affected only one side that one might get a case early enough to have one side getting well before the paralysis on the other side developed. Many unilateral cases occurred and were not recognized because the rest of the diaphragm on the other side was doing the work. How should one recognize the unilateral and bilateral forms of paralysis. Litten's phenomenon on the affected side was absent, there was no abdominal respiration on the paralyzed side, and the x-ray picture showed an immobile diaphragm on one or both sides. The hypoglossal and glossopharyngeal muscles supplied by these two nerves became involved and there was an inability to swallow and the secretions fell back into the bronchi and the patient being unable to cough drowned in his own secretions, after having developed a bronchopneumonia. As to therapy, a great deal had been said about artificial respiration by various methods. There was absolutely nothing to be expected from them. The patient finally died because he could not contract his diaphragm, which caused a peculiar paralytic cough. Treatment had to be directed to the site of the paralysis. If but one side was paralyzed one should use strychnine injection on the paralyzed side at the site of the sixth intercostal space. This stimulated the long respiratory nerve of Bell to bring aid to the embarrassed respiration. These cases of unilateral paralysis recovered if one got them in time, and they were kept alive long enough by stimulating the respiratory centers. It was important to keep the bowel empty, as a distended bowel elevated the diaphragm, contracted the lung, and made complete respiration impossible.

Dr. BORDEN S. VEEDER of St. Louis, Mo., said there was one point in which he agreed with the previous speaker and that was that these cases occurred more often than was recognized. Some degree of phrenic nerve paralysis was often overlooked. He disagreed with the statement that these cases were hopelessly fatal. He had seen the case referred to in the paper which was treated by the Erlanger apparatus. He had seen two other cases of postdiphtheritic involvement of the phrenic nerve and both cases recovered, so he felt that the prognosis was not absolutely hopeless.

Dr. EDWIN H. PLACE of Boston said that one of the speakers had referred to paralysis of the pharyngeal muscles and that the secretions caused hypostatic pneumonia. In private cases and in a large number of hospital cases the effort was made to turn the patient from side to side and the foot of the bed was elevated so that the secretions flowed out of the corner of the mouth. If the diaphragm was in a bad position it embarrassed other muscles, so an effort should be made to keep the diaphragm at the lowest level. To do this it was important to avoid distention of the bowels.

Dr. BARBOUR of Milwaukee said that the New York men had outlined a treatment for postdiphtheritic diaphragmatic paralysis which was very agreeable to listen to. He cited the case of a child 9½ years of age with a mild diphtheria who was injected on the third day with antitoxin. When, in the course of his duties as health commissioner he called on the child, he found him up and playing on the third day after the injection of the antitoxin. The mother said the doctor had not forbidden his being up. He told the mother that if he were the family physician his advice would be to keep the child quiet, and on a light diet. When he called at the house two days later there was crepe on the door; the child had fallen over dead. Drugs were of little benefit in postinfectious conditions, but rest in bed in a dark room and light diet were very important.

Dr. E. C. FLEISCHNER of San Francisco called attention to several simple procedures that might aid one in making an early diagnosis of postdiphtheritic paralysis. These were routine daily observations with reference to the knee jerks and other reflexes, particularly the palatal reflex. Postdiphtheritic nerve involvement might be avoided if proper attention were given to rest over a sufficiently long time.

Dr. A. F. M. GREENY of Fergus Falls, Minn., asked for information with reference to the case of two boys

who had an attack of mild pharyngitis and later involvement of the nasal mucous membrane. Five weeks later they began to suffer from difficult swallowing and regurgitation, then entire paralysis of speech and involvement of the limbs. They became helpless. One of the boys died and the other recovered. At the time they had the sore throats they were given only palliative treatment but no antitoxin. The physician in attendance claimed they had had a streptococcus infection. The surviving boy was extremely nervous and irritable. Dr. Greeny asked what the prognosis was with reference to the nervous symptoms and what the opinion was as to the diagnosis in this case.

Dr. MIXSELL, in closing the discussion, said there was not much he wished to add to the paper, but he might lay emphasis on some of the points brought out by the men who had discussed the paper. The importance of the early administration of antitoxin should be emphasized. In certain parts of New York City clinicians held that all cases of tonsillitis whether they looked like diphtheria or not, if there was any doubt as to the diagnosis, were given antitoxin. Dr. Berg brought up the question of the injection of strychnine, personally he had failed to see much benefit from the injection of strychnine into the diaphragm or elsewhere. He might be wrong. He agreed with Dr. Veeder that the various forms of artificial respiration should be employed. If two or three cases had recovered so far as we now knew that was the only way of bringing them through. He agreed also with what had been said about rest, they would like to keep these children in bed five or six weeks after the administration of antitoxin and they were planning to do it at Willard Parker. Dr. Fleischner's suggestions were very important; they made a daily examination on those points in almost all of their cases, probably all. Dr. Greeny's cases might be postdiphtheritic diaphragmatic paralysis or they might be something else, possibly encephalitis, but the doctor might have gone ahead with the antitoxin whether the cultures were positive or not. One should not rely upon one negative culture, but should send cultures to several laboratories if necessary before deciding that the cultures were negative.

(To be concluded.)

Books Received.

The MEDICAL RECORD is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading; but this is with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.

MICROBIOLOGY. Edited by CHARLES E. MARSHALL. 1043 pages with 200 illustrations. Published by P. Blakiston's Son & Co., Philadelphia.

MANSON'S TROPICAL DISEASES. Edited by PHILIP H. MANSON, M.D. 960 pages with illustrations. Published by William Wood & Co., New York.

TRAUMATIC SURGERY. By JOHN J. MOORHEAD, M.D. 864 pages with illustrations. Published by W. B. Saunders Company, Philadelphia.

MONOGRAPHS OF THE ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH. No. 14, Feb. 1, 1921. 42 pages. Published by the Rockefeller Institute for Medical Research, New York.

THE JOHNS HOPKINS HOSPITAL REPORTS. Volume XX. Fasciculus 111. 314 pages with illustrations. Published by the Johns Hopkins Press, Baltimore.

MEDICAL NOTES. By SIR THOMAS HORDER, M.D. 112 pages. Published by Henry Frowde and Hodder & Stoughton, London.

GRAPHIC METHODS IN HEART DISEASE. By JOHN HAY, M.D. 178 pages with illustrations. Published by Henry Frowde and Hodder & Stoughton, London.

THE SCIENCE OF OURSELVES. By SIR BAMPFYLDE FULMER, M.D. 326 pages with illustrations. Published by Henry Frowde and Hodder & Stoughton, London.

THERAPEUTISCHE TECHNIK. Edited by JULIUS SCHWABE. 1117 pages with 666 illustrations. Published by Georg Thieme, Leipzig.

Antianaphylaxis and atropin, prevention of acute arspenamine reaction by, 882.

Antibodies, the local formation of, 484.

Antigens, entero, in practice, 19.

Antimony in the treatment of epilepsy, 71; tartrate, further notes on the intravenous injection of. Leucodermat and skin complications; administrations of large doses, 668.

Antiserum, diphtheria, in mumps, 792.

Antisyphilitic therapy: A comparative study of some intensive methods, 793.

Antitoxin, diphtheria and toxin, 410.

Anus, malformations of the, 569.

Anxious states, opiates in, 924.

Aortic incompetence, comparative blood-pressure readings in, 1113; insufficiency and mitral stenosis, the atypical forms of, 230; lesions, the Bordet-Gengou reaction in, 510.

Apoplexy, 82; of the placenta, 883.

Apurineurosis, 973.

Appendicitis, a consideration of the postoperative mortality of, especially in children, 327; a further consideration of intestinal fistula following, 495; acute, indications for the treatment of, from the standpoint of the surgeon, 883; acute, the incidence of kidney infection in, 75; and some of the difficulties attending its diagnosis, 481; and the rubber glove, 334; chronic, so-called, 214; chronic, the diagnosis of, its relation to an enlarged cecum, 33; foreign bodies as a cause of, 325; how may we reduce the identification by methods in children, 75; in children, with a report of five hundred cases, 33; nasal sinus infection as a causal factor in, 934; retrocecal traumatic, 718.

Appendix, adherent retrocecal, a safe and simple method for the extirpation of the, 718; operation for the removal of in the quiet period, 494; utility of the, 105.

Applications, arsenical, studies concerning the influence of, upon cutaneous tissue, 441.

Arc, reflex, in abdominal reflexes, the centripetal part of the, 802.

Armstrong, John, 725.

Arrhythmia, a hitherto unemphasized form of: truer standards in the diagnosis of heart failure, 1080.

Cardiac, a general description of, 545; cardiac, auricular fibrillations, the most common and important of, 544; cardiac, remarks on the, and the identification by methods which are generally available, 43.

Arsenic, a note on the history of, in therapeutics, 679.

Arsphenamine injections, a tourniquet for, 698; reaction, acute, prevention of by antianaphylaxis and atropin, 882.

Arteries, a study of the condition of the, in a uterus removed twenty-four days after delivery: vascular changes during uterine involution, 806; common carotid, pulsating exophthalmus cured by ligation of both, 845; coronary, thrombosis of the, 74; coronary, thrombosis of the: a clinical and pathological study, 365.

Arteriosclerosis, relation of intestinal fermentation to, 325; therapeutic management of, and its relation to the etiology of the disease, 971.

Artery, common iliac, preliminary ligation of, in hip joint exarticulation, 335; renal, intermittent spasm of the, with report of two cases, 978; rupture of the, 579; uterine, spontaneous rupture of, during confinement, 102.

- Arthritis, acute infective, 1113; and rheumatoid conditions, the nature of, 69; Benjamin Rush on the relation of diseased teeth to, 813; chronic, nature and treatment of, 677; dietetic treatment of, with special relation to maximum fat feeding, 830; rheumatoid, treatment of, by vaccines, 70; special treatment of, 891; the role of the prostate and the seminal vesicles in, 831; treatment of, by drugs, 890; treatment of, by nonspecific therapy, 920.
- Arthropathies, sclerodermic, 145.
- Arthroscopy, A concept of x-ray pathology, 259.
- Asphyxia, some surgical aspects of, 670.
- Aspiration, direct, of the contents of the biliary tract through the duodenal tube, 73.
- Asthma, ancient dietary rules for, 680; and anaphylaxis, 669; appendicular, 274; bronchial, effects of x-ray treatment of the hypophysis in, 282.
- Athletics for girls, 969.
- Atresia of the ileum with microcolon, the report of a case of, 417.
- Atrophies, progressive spinal muscular, of syphilitic origin, 19.
- Atropine, antianaphylaxis and, prevention of allergic asphenanadium reaction by, 882; the effect of small doses of, on the heart rate, 932; the use of, in the treatment of the asthmatic infant, 72.
- Auricular fibrillation, 527; fibrillation, the most common and important of cardiac arrhythmias, 544; flutter and fibrillation in pregnancy, 846.
- Autotransfusion for hemorrhage, 58.
- B**
- Babies, bottle, anhydrous dextrose in the feeding of, 164; breast-fed, who cry at night, 115.
- Baby week council, National, 581.
- Baby's milk, the, 527.
- Bacache, a consideration of low back pain of a mild type, 734; gynecological, 239.
- Bacillus, Friedländer's, the mechanism of the carrier state with special reference to carriers of, 409; Morgan's, 495.
- Bacteria found in the throats of healthy people, the significance of, 759.
- Bactericidins, the production of, by microorganisms, 972.
- Bacteriology of the alimentary tract, the changes on the 279; of infected wounds with special reference to the importance of streptococcus hemolyticus, 409.
- Baldwin, J. F., cause of death from nitrogen oxide-oxygen anesthesia, 266.
- Bant's disease, splenectomy in third stage, with report of a case of fifteen months' standing, 417.
- Barnes, George Edward; a tourniquet for arsenamine injections, 638.
- Basile, fifty years of cancer mortality in, 950.
- Basal metabolic rate, the fundamental classification of diseases by the, 156; metabolism, see also *Metabolism*.
- Batley, Dr. Robert, monument to, 927.
- Beans, poisonous, 199.
- Beebe, S. P.; iodine in the treatment of gonorrhea, 996.
- Behan, R. J.; triple calcium phosphate as a stimulation for bone reproduction (healing) in fractures, 650.
- Belgium, tuberculosis in, of the contents of the, through the duodenal tube, 73; tract lesions, gallbladder and, pathogenesis and physiopathology of, 111.
- Bill, maternity center, 706; Sheppard-Towner, opposition to the, 1013; tuberculosis, interesting figures in connection with, 870.
- Bills, narcotic, before Governor Miller, 703.
- Biochemistry of germs and other problems, researches on the, with special reference to the problems of immunity, 882.
- Biology, variability in, 755.
- Birth rate, French, 753; rate in England and Wales, 879.
- Bladder, tumors of the, 850.
- Bleeding, the intravenous injection of sodium citrate a new method for the control of, 785.
- Blind, can the, see, 443.
- Blindness, snow, 194.
- Block, Siegfried; Insanity, A broad review for the general practitioner, 1055.
- Blood cells, behavior of, under varying conditions, 145; chemistry, a review of three hundred cases of, 881; constituents, physiochemical relationship between, 836; increased amount of uric acid in the, in the toxemias of pregnancy, 881; origin of dietary origin, 959.
- Blood, leukemic, myelocytic variations in, during treatment, 505; physiology, in infancy and childhood, 1117; picture in normal and abnormal pregnancy, 893; poisoning through gum after extraction of tooth, death from, not accidental, 657; pressure on the, during intravenous injection of quinine, 198; pressure, action of digitalis and atropine on the, 1113; pressure, altered, as a manifestation of imbalance, 31; pressure, mental effort, 705; pressure apparatus, errors and oversights in the use of the, 82; pressure, behavior of, during the use of the stomach tube, 933; pressure findings, a rational interpretation of, 196; pressure guides in anesthesia and surgery, 32; pressure increased, the influence of protein food on, 158; pressure, raised, 236.
- Blood, serial, observations on man, an automatic method for, 1076; pressure variations, the interpretation of, 1076; observations on, pressure variations and the relations of the adrenals and the autonomic nervous system to the production of blood pressure, 667; serum, interpretation of Wassermann reaction of, in mental diseases, 327; tests for workers, 1016.
- Blood, high, the relationship of, to furunculosis, 251; the relation of the liver to the difference value of the, 1072; transfusion of, 1114; the transfusion of a body, the relations following, 624; transfusions, factors in reactions after, 628.
- Bloodless surgery in flat-foot, 921.
- Board of Health, State, Alabama, a review within its power in making State medical association, the, 789.
- Bochroch, Max H.; early and important symptoms of mental disease, 929.
- Bodies, foreign, in the abdomen, 788; foreign, See also *Foreign Bodies*; loose, in joints, 933; movable, in the knee-joint, 417.
- Boehme, Gustav F.; Some fallacies of Christian Science, 395.
- Bone graft, nonunion of the humerus; repair by means of the, 75; necrosis with special reference to tuberculous lesion, 80; of Vesalius discovered by radiography, 324; reproduction (healing) in fractures, triple calcium phosphate as a stimulation for, 650; setters, osteonaths, and physical therapists, 582.
- Bones, secondary tumors of, 456.
- BOOK REVIEWS:**
- A Naturalist on Lake Victoria, with an account of sleeping sickness and the tse-tse fly, by G. D. Hale Carpenter, 367.
- After-treatment of surgical patients, by Willard Burt, 585.
- Aids to Osteology, by Philip Turner, 585.
- American Red Cross in the Great War, by Henry P. Davidson, 626.

- Symptoms, the unconscious in, 418.
- Symptoms, gastric, chemistry of the, 331; neurological, occurring in pernicious anemia, especially antedating the appearance of the blood picture, 942; of disease, the theory of disturbed reflexes in the production of, 109; signs and, gastroenteric, interpretation of, 938; the importance of the study of, with a discussion of Mackenzie's law governing their causation, 1078.

Synopical accidents, localized pleural irritation and, 763.
 Syndrome, incomplete. Millard-Gubler, 58; Klippel-Feil, 753; migraine-epilepsy, the familial distribution of the, 153; pallid, 1103.
 Syndromes, endemic, the classical, 493; love as a cause of disease, 273.
 Synergistic analgesia, 889.
 Syphilis, acute, nephritis in, 1022; alcohol and, as a cause of mental disease, 757; and diabetes, 198; clinical, of the central nervous system, 605; coexistence of demotrophic and, 417; involvement of nervous system during primary stage of, 112; latent, in pregnancy, 355; of the lung simulating tuberculosis, 1071; of the nervous system, clinical versus laboratory findings, 56; sero-diagnosis of, 931; syndrome of lethargic encephalitis apparently caused by, 1039; the urine in, 156; treated, the cerebrospinal fluid in, 582.
 Syphilitic, the latent, an experimental study of, as a carrier, 197.
 Syphilitics, the Wassermann reaction in the transudates of the, 19.
 Syphilography, recent developments in, 13.
 Systems, sympathetic and parasympathetic, the special service rendered to the human organism by the, including both nerves and glands of internal secretions, 934.

T

Tabs, juvenile, 450; mesenterica following influenza, 239; neosylvarsen and mercury in, 1111; the early of recognition, 528.
 Tapping of the heart, 538.
 Tattoo marks, removal of, 923.
 Tax, income, fund owned by hospital and not paid on, 961.
 Taylor, J. Madison: reestablishment insurance, 648.
 Tea intoxication, 463.
 Teeth, and systemic disease, 945; diseased, Benjamin Rush on the relation of, to arthritis, 813.
 Temperature control as related to improvement in milk, cream, and butter supplies, and how it should be applied, 565; record, quasi-continuous, the value of, in the early diagnosis of tuberculosis, 714.
 Temporomandibular articulation, bony ankylosis of the, 718.
 Tension, heat and, clinic, 322.
 Test meals of Ewald and Boas, the chemical estimation of gastric function by the, 714.
 Testicular extract, commentary on a case of hysteria-epilepsy with delayed puberty treated with, 70; grafting, 704; grafting, a eunuch on, 575; onotherapy, 105.
 Testimony of habitual user admissible that substance purchased was opium, 440.
 Testing for glasses, eliminative subjective, 117.
 Tests, blood, for workers, 1016; functional, clinical, record of twenty-five selected cases of renal disorders illustrating various functional tests, 940; physical efficiency and level oxygen, a record of experience with certain, 715.
 Tetanus, action of curare in, 935; post-seric, 62; psychogenic, 20; with recovery, showing some unusual features, 786.
 Therapeutic Hints, 42, 126, 210, 336, 548.
 Therapeutics, physical, bone setters, osteopaths and, 582; physical, in New York hospitals, 737; the scope of in the relief of narcotism, 250.
 Theodor, Emil: the advantage of, in organic nervous disorders, 590.
 Thompson, W. Gilman: centenarians and over, 404; the teeth and systemic disease, 945.
 Thoracic cavity, studies on the effect of trauma in the, 627.
 Thorax, severe rachitic involvements of, and certain of their consequences, 368.
 Throat, nose and, diathermy in diseases of the, 494.
 Throat, human, experimental inoculation with avirulent diphtheria bacilli, 759.
 Thromboangitis obliterans (Berger's disease), intravenous citrate of soda treatment of, 370.
 Thrombophlebitis, postoperative, 77.
 Thrombosis of the coronary arteries, 74;

of the coronary arteries; a clinical and pathological study, 365.
 Thunb, effect of the development of the, through the eye of modern man, 841.
 Thymic, distension, 383.
 Thymus and mammary, the effect of, on menstruation, 326; gland, the relation of the persistent to criminology, 438.
 Thyroid, adenoma of the, with hyperthyroidism (thyrotoxic adenoma), 538; basal metabolism as an index of treatment in diseases of the, 756; cases, laryngeal function in, 333; 847; gland, the interrelationship of the, and of its active agent, thyroxine, in the tissues of the body, 1076; preparations, 277.
 Thyroids, ligation of the superior, in patients with exaggerated toxic symptoms, 75; the influence of the, on the functions of the suprarenals, 283.
 Thyroxin, the interrelationship of the thyroid gland and its active agent, the tissues of the body, 1076.
 Tick fever, a form of, 199; an experimental investigation of *Spirochaeta duttoni*, the parasite of, 157.
 Tissue, the reducing power of the, 199.
 Tobacco and infant mortality, 1048.
 Tonsil and adenoid situation in New York City, 844; and sinus surgery, nitrous oxide-oxygen anesthesia for, in the forward inclined sitting posture, 32.
 Tonsillectomy and adenoidectomy, some remarks on, 641; beneficial effects of, on cyclic vomiting, 1117; late results of, 720; the value of vaccine therapy versus, in systemic disease of tonsillar origin, 300.
 Tonsillitis, acute lacunar, renal complications of, 29; gangrenous, cured by antigangrenous serum, 41.
 Tonsils and scarlet fever, 418; from a clinical and pathological standpoint, 157; hypertrophic, the roentgenography of, by Roentgen ray, 240; operations on the during sepsis, 801.
 Tooth, death from blood poisoning through gum after extraction of, not accidental, 657.
 Toothache, 126.
 Tothet J. W.: some practical points in cases, 866.
 Tournefort for arsenamine injections, 698.
 Toxemia of pregnancy, increased amount of uric acid in the blood in the, 881.
 Toxin antitoxin, diphtheria and, 410; diphtheria with Schick test and immunization with, 535.
 Tracheotomy, intubation versus, in laryngeal diphtheria, 116.
 Transfusions, blood, factors in reactions against, 683; blood, transfusion for, 201; blood, precautions necessary in the selection of a donor for, 112; blood, symposium on, 201; of blood, a study of the reactions following the, 624; repeated, serious reactions to, in pernicious anemia, 1021.
 Transplantation, successful, of the ileocecal valve in the dog, 661.
 Transudates of syphilitic lesions, Wassermann reactions in the, 19.
 Trauma in the thoracic cavity, studies in the effect of, 627.
 Treatment of injury's findings as to, not decisive, 525.
 Triple calcium phosphate as a stimulant for bone reproduction (healing in fractures), 1048.
 Tropics, American children in the, 1113.
 Trypan blue (colloids), the fate of true solutions (phenolsulphonphthalein) and injected into the mammalian embryo, 1021.
 Trypanosome disease, sexual propagation of, 996.
 Tubercle bacilli, active immunization by means of nonvirulent and nontoxic living, 196; bacilli, albumin, lymphocytic cells and, in the sputa, 918; bacillus, artificial immunization against, 548.
 Tuberculin, a simple method of administering, that has proved efficacious, 368.
 Tuberculosis and decalcification, 925; bill, 665; bill, interesting figures in connection with, 970; committee, summary of the work of the Philadelphia Health Council and its conference, 752; diagnosis in, 1055; differential diagnosis of, 27; experimental sulphur dioxide as a method of treating, 1093; fighting, 66; in Belfast, 108; in cattle, measures for the control of, 206; in childhood, apex, hilum and lower

lobe lesions of; their relative frequency, 789; in children, a clinical study of, 773; in man and animals, eradication of, 713; inhibitory action of sodium citrate in, 278; intestinal, 937; kidney, 76; of the kidney in women, 409; of the pericardium, 979; phthisis and, death resulting from, 583; presumption of, from external stigmata, 68; problem in Europe, some aspects of, 206; psychotherapy of, 82; pulmonary, in adults, apical rupture, insufficiency and the diagnosis of, 272; pulmonary, some deductions from the statistics on the prevalence of, 153; pulmonary, Spahlinger treatment for, 540; pulmonary, the right ventricle in, 544; pulmonary, the treatment of, 620; pulmonary, the value of the pneumothorax treatment of, 668; resistance to: a non-immunologic chemical factor worthy of consideration, 546; roentgen ray and, in infants and children, 1024; sales of raw caribs in, 401; sanatorium mismanagement of, 361; some interesting things about, 56; Spahlinger serum for, 1070; surgery, in children, the treatment of, by, 1048; hyperemia, 1011; surgical, sanatoria for, 362; the educational campaign against, Pennsylvania, 205; the effect of the influenza epidemic on, 82; the mechanical treatment of, 242; the results of sanatorium treatment for, 33; the treatment of, with sodium morrhuate, 1048; the value of the quasi-continuous temperature record in the diagnosis of, 71; urological, report of a case of, 832; vaccination, 1048; what about a cure or preventive of, 769.
 Tuberculous ex-soldier, what the United States Government is doing for the, 205; psychology of the, 529; relative frequency of dental caries in the, 615.
 Tumor, Krukenberg, of the ovary, 1022; of the spinal cord and its membranes, 83.
 Tumors, fibroid, myomectomy vs. hysterectomy, x-ray in the treatment of, in women under forty years of age, 91; newer aspects of the clinical study of, 288; of the bladder, 950; of the bone, secondary, 1045; of the kidney, 850; of the ovary, in children, 363; ventral, of the sacrum, removal of, by the posterior route, 415.
 Twin monster, 893.
 Typhoid carrier, from the laboratory, medical, and surgical standpoints, 58.
 Typhoid carriers, the surgical treatment of, 69; clinical, the eradication and, 232; fever, the value of extensive inoculation of a community during an epidemic of, 157.
 Typhus, epidemic, 1045; fever, a report of the public health committee on, 488.

U

U. S. Public Health Hospital at Fox Hills, Staten Island, baseless criticism of, 574.
 Ulcer, duodenal, gastroduodenostomy, versus posterior gastroenterostomy, in the treatment of, 887; gastric, an investigation of the cause and relief of pain in, 150; gastric and duodenal, 333; gastric and duodenal, early diagnosis of perforated, 98; gastric and its treatment, 902; gastric and duodenal, the dietetic treatment of, 115; gastric and duodenal, the early diagnosis and treatment of, 74; of the jejunum following gastroenterostomy, 326, 333; perforated gastric, 972; of the stomach and duodenum, specialization in the medical and surgical treatment of, 727; persistence of pyloric and duodenal following simple closure of an acute perforation, 614.
 Unconscious, the, in spirit communications and telepathy, 41.
 University College, London, medical developments at, 405; of Paris, incumbents of the chair of obstetrics at the, 199.
 Uremia and pulsus alternans, coincidence of, 1022; of nurslings, 922.
 Ureter, wound of, the, 802.
 Ureteral calculus, 76; picture and pyelitis, an analytical study of 50 cases of, 332; stricture in the male, 76.
 Uric acid, increased amount of, in the blood in the toxemias of pregnancy, 881.

Urinary tract, the combined examination of the, by the urologist and the roentgenologist, 77.
 Urine, diagnostic points of value found in the, 465; new and simple tests for alkaline carbonates in, 516; the, in syphilis, 156.
 Urobilin, chemistry and clinical significance of, 497.
 Urobilinuria, the physiopathology of, 400.
 Urology: Its place in medicine, 1058.
 Uronephrosis, the pathological physiology and symptomatology of, 355.
 Uterus, a study of the condition of the arteries in a removed twenty-four days after delivery; vascular change during uterine involution, 800; action of quinine on the pregnant, 407; acute inversion of the, 756; cancer of the, 243; gravid cesarean section for penetrating wounds of the, 848; radium in carcinoma of the, 244.

V

Vaccination against tuberculosis, 1048; animal, priority of Italy in, 768; smallpox, a new site for, 68; phagadenic, 136.
 Vaccine therapy in regard to general practice, 537; therapy tonsillotomy in systemic disease of tonsillar origin, the value of, 300.
 Vaccines and drugs, proposed state control of, 533.
 Vaginal outlet, relaxation of the: is the obstetrician responsible, 332.
 Vaginitis, ulcerogangrenous, from fatal mercurial intoxication, 625.
 Valles, Doctor Francisco, Spanish precursor of Bacon and Descartes, 84.
 Valve, iliocecal, successful transplantation of the, in the dog, 661.
 Van Schnick, George C.: observations on the treatment of incoercible vomiting of pregnancy, 746.
 Variability in biology, 755.
 Vendors, itinerant, of drugs, construction of statute as to, 187.
 Vineberg, Hiram N.: myomectomy vs. radium and x-ray in the treatment of fibroid tumors in women under forty years of age, 91.
 Venereal disease, commission to the Far East, British, 798; in the British army on the Rhine, 665; prevention of, 533; self disinfection in, 280; the abolition of, 854; the prevention of, 109; diseases, cost, of to the Army, 42; diseases, some thoughts suggested by the campaign against, 23; diseases, the question of compulsory notification for, 330; question, the, 754.
 Ventricle, the, fight in pulmonary tuberculosis, 544.
 Verminosis, presumption of, 347.
 Vertigo, the significance of, 74.
 Vesalius, none of, discovered by radiography, 324.
 Vesicles, seminal, the prostate and the role of, in arthritis, 881.
 Vesiculitis, seminal; a study of 1000 cases, 76.
 Virus, rabies, is there a plurality of, 965.

Viscera, abdominal, pain in diseases of, 452; care of, kept for analysis in homicide cases—admissibility of evidence of result, 354.
 Vision, color, 371.
 Vital statistics of 1919, 665.
 Vitamines, a German manifesto on, 797; and inanition, 173; Magendie's, anticipation of the discovery of, 486; similarity of effects produced by absence of, and by exposure to x-rays and radium, 1020; the question of, 866.
 Volvulus of the intestine, 868.
 Volstead law, protests against the, 1015.
 Vomiting, cyclic, tonsillectomy in, 1117; incoercible, of pregnancy, observations on the treatment of, 746.
 Von Bunge, death of, 1042.
 Von Tuck, Karl, and Flack, Roswell, E.: vaccination against tuberculosis, 1048.
 Vulva, photogravures of a case of large hematomas of the, 119.

W

Walther, H. W. E.: urology: its place in medicine, 1058.
 Walker, Norman: panel doctors in the British army, 619.
